**Dark Cell Adenocarcinomas of Kidney.**—Fryfogle and his associates show that two factors contribute to the continued use of the term "hypernephroma," even though the origin of cortical carcinomas is now established as being the renal parenchyma: (1) the historic use of the term and the extreme controversy when it was introduced and (2) the confusion of names applied to cortical malignant lesions by radiologists and pathologists. The abundance of patterns seen microscopically in cortical malignant lesions should be proof of the inadequacy of classification on this basis. Cytology as a basis for classification has been dismissed because dark cell and clear cell strands are usually seen in the same tumors. For these reasons teachers have been reluctant to discard the term "hypernephroma," which, although it is genetically false, is understood by all to mean a malignant renal tumor. For the sake of clarity the authors too have used the term "hypernephroma" in the microscopic reports, but after being confronted with a lesion that in no way, gross or miscroscopic, resembled Grawitz' original description, examining all the other "hypernephromas" removed at the Mayo Clinic and writing this paper, they are convinced that the dark cell adenocarcinoma is a tumor entity in itself and deserves recognition as such. Of the 768 tumors studied, 29 were of the pure dark cell type, making an incidence of 3.8 per cent. Their diagnosis cannot be made, as such, preoperatively, but it is suspected by alteration of gross color and ill defined encapsulation and is proved by multiple microscopic sections showing only the dark granular cells. The tumors differ from mixed and from clear cell adenocarcinomas in that they contain little or no intracellular fat, that they appear to occur more frequently in women than in men and that a mass is the symptom of which most frequent complaint is made. They frequently calcify and, regardless of size, if the tumor is removed before extrarenal extension occurs, the patients, especially the women, have long term survivals. Prognosis in this small series was somewhat better than for hypernephromas. The five year survival rate for men was 25 per cent (2 of 8) as compared with a 67 per cent (8 of 12) five year survival rate for women. Also, all of the long term survivals were of women. These were twenty-one, twenty-two and thirty-one years postoperatively.

**Life Expectancy in Cancer of Prostate.**—Beatty reviews 88 cases of carcinoma of the prostate, 68 of which had been reviewed previously. Data on the recent 20 cases are presented. Duration of symptoms prior to diagnosis varied in these from one month to one year, with an average of six months. With periodic rectal examinations as a routine procedure in all adult males, urologists can hope for still further reduction in this latent period. Prostatectomy was performed in 4; resection in 8, and castration in 6. All patients except those castrated have received diethylstilbestrol orally. Results in the 20 cases were as follows: improved, 14; failures, 3; deaths, 2, and lost to observation, 1. Of the entire series of 88 patients 35 are still living; 26 have died, and 27 are lost to observation. Of the 35 living patients, 21 are definitely improved and 14 have been classified as failing. The average survival time of the 35 so far is two years; for the 26 who have died it was 2.73 years. Since Aug. 1, 1946, when the statistics of this paper were compiled, a resurvey of the 35 living patients was made. Seven patients have died; 5 are failing; 4 have been listed as incompleted data and 19 are still in good health. Analysis of the 7 who died discloses: One survived seven years; 2 survived five years; 3 survived three years and 1 survived two years. Six of the 7 patients had either castration or resection or both performed. All 7 had taken diethylstilbestrol over long periods. Remembering the hopeless condition in which earlier patients spent their remaining days the author concludes that present conditions are much more hopeful. The new regimen renders patients more comfortable, and they live relatively normal lives for about twice as long. Many of them, instead of waiting for death, assume their former places in the community.

**Prognosis of Testicular Tumors.**—Ormond and Best point out that prognosis of testicular tumors in men of military age is unfavorable. These reports prompted them to survey their own cases, which were not restricted to men of military age. They analyzed the 40 cases of malignant tumors seen at Henry Ford Hospital between the years 1923 to 1946 inclusive. The average age of their patients was 37.8 years. Average duration of symptoms before the patient presented for treatment was 13.9 months. The three-year survival rate, irrespective of metastases, in patients under 30 years was 16.6 per cent; in those over 30 years, 57.1 per cent. Metastases were present in slightly over one third of the patients at the initial examination. Metastases appeared earlier and more frequently in young men (under 30). The prognosis is related to the presence or absence of metastases. Of 26 patients presenting without demonstrable metastases 3 are dead and 2 are untraced. Of 23 traced patients without demonstrable metastases treated by orchiectomy and immediate irradiation 21 or 91 per cent are living, periods of survival varying from one to twenty years. Simple orchiectomy with high ligation of the cord followed by postoperative roentgen therapy was utilized in this series. The prognosis of malignant tumors of the testicle has improved greatly in the past twenty-five years. Earlier orchiectomy combined with postoperative irradiation is responsible for this improvement in prognosis. Any suspicious enlargement, unusual induration or irregularity of the testicle should receive serious attention. All hydroceles should be scrutinized carefully. Operative exploration should be carried out in every doubtful case.

Continued Education of Doctors. G. L. Schadt.—p. 878.

**Allergic Parotid Swelling.**—Zindler and Fraser report a 54 year old wife of a turkey farmer, referred to one of the authors for allergy study, with the suspected diagnosis of allergic parotitis, although allergy is rarely considered in this condition. The symptoms could be reproduced by exposure to turkey feathers and on one occasion from the emanation of cooking turkey acting as an osmyl. The ingestion of certain foods such as wheat and milk likewise produced the allergic symptoms. Complete relief was afforded by the elimination of these foods and adequate specific inhalant therapy. The authors believe that this condition occurs more often than previously estimated. It is probably frequently misdiagnosed in respect to its allergic causation. Allergic parotid swelling should be included in the differential diagnosis of painful enlargements in the region of the parotid glands. The food tests proved to be practical and specific in the diagnosis of food sensitivity in this patient. The recognition of the phenomenon of masked food allergy was essential in the true evaluation of this patient's symptoms, the diagnosis of her specific food sensitivities and the successful management of her therapy.

**Overtreatment of Eclampsia.**—Mengert and Hermes report that 5 women with toxemia of pregnancy died within a relatively short time. Pulmonary edema resulting from excessive administration of fluids accounted for, or was a feature in, the deaths of each of them. In consequence, the treatment of preeclampsia or eclampsia was revised to limit the fluid intake to replacement of the daily insensible loss, calculated as 1,500 cc., plus the amount of the previous twenty-four hour urinary output. Since then, 21 consecutive eclamptic women were treated without fatality.

**Nail Changes in Arterial Disease.**—Edwards directs attention to the fact that nails undergo specific changes in vasospastic and in organic peripheral arterial disease and that these changes are senstive indicators of the severity of the arterial lesion. In arteriospastic states, changes that may be grouped under the dermatologist's term of pterygium are described. They consist of a thinning of the nail fold and a widening of the cuticle. The normal abrupt demarcation between nail fold and cuticle and between cuticle and nail plate is lost. Sympathectomy quickly restores the nail fold and cuticle to normal. In organic arterial disease there is rather thickening, roughening and darkening of the nail plate, which hides the nail bed. An increase in arterial circulation by any means gives rise to a more nearly normal growth of the plate. Less specific changes include the growth of claw nails, or the presence of "diffusion of the lunule" in organic states, and the loosening and shedding of the nail plate in severe disease of either vasospastic or organic origin. Painful nails are often an expression of the hyperesthesia of severe ischemia, in which operations for ingrown toenail usually cause gangrene. Primary infections of the nails are uncommon in peripheral vascular disease, but the nails may be involved in acral ulceration, or may show subungual abscess over an osteomyelitis of the terminal phalanx.

**Administration of Estrogen and Adenocarcinoma of Endometrium.**—Stokes reports the case of a woman, aged 65, who had not menstruated for nineteen years. For some obscure reason she was given 0.1 mg. of diethylstilbestrol for three of every four weeks. In the ensuing twenty-one months, she received about 470 doses of 0.1 mg. of diethylstilbestrol. She began to bleed in August 1943, two months after onset of treatment, and continued to do so at intervals. Administration of diethylstilbestrol was discontinued in March 1945. She was seen in the department of obstetrics and gynecology for the first time in August 1945, with a uterus two times the size of the uterus of a woman in active menstrual life. Curettage was performed and the pathologist reported: "Endometrial polyp with anaplastic changes in the epithelium and anaplasia and loss of polarity possibly due to abnormal hormonal stimulation." The uterus was removed. The uterine cavity contained an endometrial polyp. The report of the pathologist was as before, with the addition, "adenocarcinoma of the endometrium in the endometrial polyp." The author briefly reviews the literature on the relation of estrogens to carcinogenesis and shows that opinions differ. Most gynecologists agree that treatment in patients with intact uterus should be withheld one week out of the month and that the dose should be minimal. In the patient under discussion carcinoma developed in spite of observance of both these cautions.

Polyarteritis Nodosa with Pulmonary Manifestations and Cardiac Failure. M. S. R. Hutt.—p. 66.
Scrotal Pneumocele Complicating Artificial Pneumoperitoneum. H. Meltzer.—p. 70.

**Open Intrapleural Pneumonolysis.**—Smith defines open intrapleural pneumonolysis as the operation of division of adhesions between the two layers of pleura, through an incision into the pleural cavity, the division being effected under direct vision with the diathermy needle or scissors. Thirteen patients have been treated by this procedure during the last four years at Fazakerley Sanatorium. This was only a small percentage of all the patients with adhesions unsuitable for closed pneumonolysis who were treated during the four year period. The creation of a functionally sound artificial pneumothorax by open pneumonolysis has the following advantages: It does not produce a permanent collapse; the bony thorax is left intact; the operation can be completed in one stage; it produces a less mutilating and mechanically more perfect collapse than with other methods, and the control of the affected side thus obtained reduces the gravity of a spread to or extension of disease on the contralateral side. The most pertinent disadvantage is that an artificial pneumothorax space is essential to allow of thoracoscopy on the side on which the operation is contemplated. The extent to which adhesions are divided may fall short of that hoped for from the preliminary thoracoscopy, and important apicomediastinal adhesions apparently amenable to section by open operation may patently not be so when examined, the end result of the operation being worse than the primary condition. A table which gives the details of the 13 patients indicates that they were relatively young, all being less than 30 years of age and about half less than 21 years of age. The results were satisfactory in all but 3 of the patients. The author concludes that so long as relaxation of the diseased lung remains a vital matter for the patient, the possibilities of this operation should not too readily be put out of mind for the young patient with a short history of disease and a recently induced artificial pneumothorax, provided that the findings at thoracoscopy suggest the feasibility of a safe enucleation or section of adhesions by open operation, when closed pneumonolysis has failed.

Laminar Pattern of Lateral Geniculate Body in Primates. L. W. Chacko.—p. 211.

**Purulent Pachymeningitis.**—According to Schiller and his associates purulent pachymeningitis is characterized by a film of pus of variable thickness in the subdural space spreading over part or all of one or both cerebral hemispheres. It has been termed subdural empyema, subdural abscess, internal purulent pachypyema, subdural abscess, internal purulent pachymeningitis and various other names. The authors prefer the term purulent pachymeningitis. In the last twenty years the authors have observed 33 cases of spreading purulent pachymeningitis. Of these, 22 followed pansinusitis, 7 followed mastoiditis and 4 were secondary to distant foci of infection. Spreading osteomyelitis of the facial bones was associated with purulent pachymeningitis in at least 26 cases. Other associated lesions were: extradural abscess, cerebral abscess, severe leptomeningitis, thrombosis of the dural venous sinuses and/or the cerebral veins, abscess of the lungs and obstruction of the common carotid artery in the neck. In 27 cases bacteriologic tests were made and it was found that the subdural infection was due to streptococci in 25 cases (combined in one case with Staphylococcus aureus), to Staphylococcus aureus alone in 1 case and to pneumococcus in 1 case in which there was also intense purulent leptomeningitis. The streptococci were grown in 17 cases and were anaerobic in 10, alpha hemolytic in 6 and beta hemolytic in 1. Staph. aureus produces osteomyelitis of the skull as frequently as the non-beta-hemolytic groups of streptococci, but rarely spreads diffusely through the skull or produces purulent pachymeningitis as the non-beta-hemolytic streptococci do, though it frequently produces brain abscess. Before the introduction of penicillin 18 patients were treated by removal of variable amounts of osteomyelitic skull and attempts to drain the subdural space; all died. When limited amounts of penicillin became available 5 patients were treated by local instillation of penicillin into the subdural space, and all of these died. Ten patients have been fully treated with penicillin by systemic, subdural, intraventricular and subarachnoid routes. Of these 7 recovered. Purulent pachymeningitis most commonly follows operation for chronic pansinusitis or mastoiditis, and its incidence should be considerably reduced by maintenance of an adequate concentration of penicillin in the blood before, during and after these operations.

**The Agricultural Worker.**—This report by Keatinge and Littlewood is an attempt to investigate what contributions industrial and social medicine can make to assist British agriculture in its task. It analyzes the causes, economic, political and social, of the drift from the land which is the cause of today's shortage of agricultural workers, and, reviewing the conditions under which the farm worker earns his living, suggests ways by which his efficiency and status can be improved.

**Mengo Encephalomyelitis.**—Dick and his co-workers report a case of encephalitis in a laboratory worker caused by a virus first isolated from animals in the Mengo District of Uganda. When the patient had already greatly improved, he discovered that he was deaf in the right ear and had some weakness of the upper fibers of the trapezius muscle on the right side. For isolation of the virus mice, rhesus monkeys and guinea pigs were used. The serologic individuality of Mengo encephalomyelitis virus and the relationship of the monkey, mongoose and mosquito strains were established by neutralization tests. Serums collected for yellow fever immunity tests have been tested for neutralizing antibodies to the Mengo encephalomyelitis virus. Serums from 237 persons have been tested, and 3 have been found to be immune: one from the patient whose case is described here, and two from children aged 4 and 6 years, both living on the edge of the Budongo Forest in Uganda. Thus it is established that the human infection can be contracted naturally.

**Polyarteritis Nodosa.**—Tonkin and Pulvertaft consider it curious that the presence of palpable skin nodules and eosinophilia should still be regarded as the essential diagnostic criteria of polyarteritis nodosa, because for many years now authorities have shown that in only a small proportion of cases is either of these features present. The authors also stress that polyarteritis nodosa does not carry the high mortality formerly ascribed to it; 50 per cent is the mortality rate estimated by the authors. They report a case in which the clinical manifestations were observed for seven weeks and the diagnosis was confirmed post mortem. The clinical picture may be pleomorphic, but there is almost always clinical evidence of renal involvement. Two other diagnostic "sign posts" are disproportionate tachycardia and other evidence of myocardial involvement, and persistent moderate polymorph leukocytosis.

**Scrub Typhus and Tropical Sprue.**—Manson-Bahr describes preparation of an effective vaccine against scrub typhus. He calls attention to the danger of laboratory infections when Castaneda's method of growing rickettsiae in the lungs of rodents is employed, and makes suggestions as to how these can be avoided. When difficulties appeared in the large scale development of vaccine by means of cultivation of rickettsiae in the lungs of mice, a search was made for a more susceptible animal, and the cotton rat proved valuable. Buckland and others developed a method by which 600 animals yielding a maximum of 9 liters of vaccine could be handled every day. Three cases of accidental scrub typhus infections occurred among 60 laboratory workers who were exposed. All 3 had received adequate immunization and recovered. Manson-Bahr points out that during the war years, 1943 to 1945, it became evident that tropical sprue was behaving as an epidemic seasonal disease with a comparatively short incubation period. The disease observed a definite seasonal incidence from March to September, with a peak period in June, corresponding to the fly and malaria seasons. There was no association with a one-sided or deficient dietary, for one third of the number consisted of fit soldiers on full rations under favorable climatic conditions. Since the incidence of sprue preceded that of dysentery, it is unlikely that one is engrafted on the other, but postdysenteric sprue was especially noted after amebiasis.

*Streptomycin in Carrion's Disease. L. Aldana, R. Gastelumendi and J. Dieguez.—p. 323.

**Streptomycin in Carrion's Disease.**—Aldana and collaborators found by in vitro experiments that streptomycin has a bactericidal action on Bartonella bacilliformis in doses nontoxic for man. They administered streptomycin to 2 patients in the evolutional phase of acute progressive anemia and to 3 patients in the phase of verruca eruption. Excellent results were obtained in both phases. There was an immediate improvement in the severe anemia and clinical cure by the end of the treatment. The bartonella disappeared from the peripheral blood within the first three to five days of the treatment. There was rapid regression of the verrucal lesions. None of the patients in whom anemia was controlled developed verrucal eruption later. Streptomycin has a potent effect on the eruptive phase which penicillin does not have.

Fungicidal Effects of Phenol Derivatives. J. Horáček and M. Polster.—p. 342.
Skin Manifestations Associated with Lymphatic-Leukemia. C. H. Beek.—p. 350.
*Follow-Up of 400 Cases of Anogenital Pruritus With or Without Hemorrhoids Treated By Injection. C. Böhm.—p. 357.
*Question of Relationship Between Chickenpox and Herpes Zoster. Marian Fellner.—p. 373.

**Follow-Up After Injection Therapy of Anogenital Pruritus.**—Böhm says that two years ago he reported on treatment of varicosities of the anal region with subcutaneous injections of quinine-urethane and on alcohol injections in anogenital pruritus. Four hundred patients in whom from one to four years had elapsed since treatment were called in for control examinations. It was found that in the majority of cases the injection treatment of the varicose anorectal complex with quinine-urethane and the alcohol treatment of the anogenital pruritus were successful. A number of case histories are presented and observations on the others are recorded in tables. The author believes that in cases in which hemorrhoids are absent or minimal, conservative measures should be tried before the injection treatment is instituted.

**Relation Between Chickenpox and Herpes Zoster.**—Fellner reports histories of 3 children who contracted chickenpox. First chickenpox developed in a boy, aged 7. Seventeen days later chickenpox appeared in a cousin, a little girl of 2 years, and eleven days later an older sister of this little girl showed the exanthem of chickenpox. Herpes zoster appeared in the mother of these 2 girls five days after the chickenpox had developed in the older girl. Whereas in the first 2 children the chickenpox took a mild course, the third child had an extremely severe eruption and serious general manifestations, probably due to the simultaneous occurrence of herpes tonsurans vesiculosus, which probably induced hyperallergy in the skin.

### **35:**13-22 (July 15) 1948

*Prothrombinopenic Effect of Penicillin in Men. Z. A. Lewitus and A. Aschireli.—p. 13.
Complement Fixation Test for Cancer. H. J. Koebler.—p. 15.

**Thrombopenic Effect of Penicillin.**—A study of 31 patients, most of them injured in war, who received penicillin revealed to Lewitus and Aschireli that there was a tendency for the prothrombin to decrease to 50 and 60 per cent of normal under the influence of treatment with penicillin. This effect could be counteracted by the intramuscular injection of 5 mg. of a vitamin K preparation. Thus penicillin, like the salicylates and some of the sulfonamide drugs, exhibits a prothrombinopenic effect that can be counteracted by vitamin K. The authors stress this observation in view of possible cumulative prothrombinopenic effects in cases of primary prothrombinopenia, or during the treatment of patients with "dicumarol," which patients may also receive penicillin.

*Sexual Function and Epilepsy. J. J. H. M. Klessens.—p. 2154.
Silent Cases of Hemolytic Disease of the Newborn. S. I. De Vries. —p. 2159.
Congenital Diaphragmatic Hernia. E. van Wijk and S. van Creveld. —p. 2169.

**Sexual Function and Epilepsy.**—Klessens points out that epilepsy usually develops during the prepuberal age and is frequent in those in whom the first menstruation is delayed. Reduction or cessation of the menstrual flow may be accompanied by recurrence of attacks. The author cites the case of a girl in whom epileptic attacks became less frequent and gradually subsided completely as the menstrual function became normalized between her seventeenth and twentieth year. The author has also seen at least 8 male patients between 18 and 24 years of age with deficient sexual development (indicated by absence or extreme rarity of discharge of semen) who were subject to grand mal or petit mal seizures. In 2 such patients, aged 20 and 24, respectively, whose sexual development was retarded, treatment with sexual hormone for six to eight months promoted the sexual development and first reduced and then counteracted epileptic attack, which formerly had occurred almost daily. The author believes that although the electroencephalogram reveals changes between the attacks in patients subject to epileptic seizures, this does not necessarily indicate that the primary cause of epilepsy is in the brain.

Use of Curare with Electric Shock Therapy. A. Hutter.—p. 2220.
*Treatment of Syphilis During Pregnancy. J. C. Grosfeld and L. van der Lugt.—p. 2237.

**Treatment of Syphilis During Pregnancy.**—Grosfeld and van der Lugt studied the fate of children resulting from thirty pregnancies in which the syphilitic mothers had received various forms of treatment. The best results were obtained when 4,000,000 units of penicillin had been administered in addition to a course of bismuth compound and neoarsphenamine.

Can BCG Vaccination Entail Transient Decrease of Resistance? Review. J. Bøe.—p. 1411.
Intravascular Aggregation of Erythrocytes in Pregnancy, Parturition and Puerperium. H. Zilliacus and C. A. Ehrenrooth.—p. 1415.
Results of Treatment of Sterility in Women. J. Hoffmeyer.—p. 1420.
Mass Poisoning from Methyl Alcohol and Antifreeze Solution. R. Opsahl. —p. 1431.
*Hepatic Calculus and Indication for Choledochoduodenostomy. S. Müller. —p. 1433.
Osteomyelitis in Patella Treated with Extirpation. C. Holm.—p. 1434.

**Hepatic Calculus and Indication for Choledochoduodenostomy.**—Müller says that hepatic calculi were found in 36, or 3.5 per cent, of 978 patients operated on for gallstones. The permanent results of the operation were satisfactory when the calculi were few or small, unsatisfactory when they were numerous or large. Because of the considerable danger of occlusion or recurrent gallstone colic, primary choledochoduodenostomy is believed to be indicated in cases in which hepatic calculi are numerous or large.

*Complications Affecting Spinal Cord in Chloroma and Myelosis. G. Holmberg.—p. 1463.

**Complications Affecting Spinal Cord in Chloroma and Myelosis.**—In the case of chloroma reported in a woman aged 20, the spinal cord was compressed by an intraspinal infiltration in the lower thoracic segment and paraplegia resulted. Holmberg states that spinal cord complications, common in chloroma, which is a special form of myelosis, are rare in other myeloses. Chloroma was not diagnosed in any of the 41 cases of myelosis, 32 chronic, 9 acute or subacute, treated in Karolinska Sjukhuset from 1940 to 1946. Symptoms from the nervous system were seen in 2 of the cases of chronic disease.

*General Considerations on Antagonistic Complexes. G. Ramon and R. Richou.—p. 625.
*Aggravating Influence of Administration of Testosterone on Early Cancer of the Breast. P. Santy and M. Dargent.—p. 626.
Pronounced Faciolingual Apraxia in Course of Traumatic Global Aphasia. J. A. Chavany, F. Thiébaut, J. Sicard and J. Pecker.—p. 627.

**Antagonistic Complexes.**—Experiments carried out by Ramon and Richou resulted in the discovery that certain culture filtrates of Bacillus subtilis, of Penicillium notatum and of Actinomyces griseus contain antidotal, virucidal and diastasic principles in addition to the well known antibiotic principles. They therefore deserve the term "antagonistic complexes" which has been coined for them. Purified penicillin or streptomycin does not contain these additional principles. The antagonistic complexes may be substituted for the purified antibiotics in the local treatment of certain infections or toxinfections. The indications for the antagonistic complexes which have penicillin or streptomycin as base may be the same as those for the antibiotic substances themselves.

**Testosterone in Early Cancer of Breast.**—Santy and Dargent treated 8 women between the ages of 30 and 51 years with pathologic conditions of the breast diagnosed as "cystic mastopathy" by one or two intramuscular injections per week of 5 to 10 mg. of testosterone. Treatment resulted in increase in pain or in induration which characterized the lesions before testosterone treatment was instituted. There was a rapid increase in the growth of the tumor which was first considered benign. In 6 of the cases cancer of the breast was diagnosed on clinical examination and only in 1 case degeneration of a cystic mastitis was demonstrated on clinical and microscopic examination. Because of the small doses of the drug employed and the rapid development of the cancer it is suggested that in the majority of the cases the androgen had a stimulating effect on a latent cancerous lesion or on a precancerous lesion rather than a cancerogenic effect. With regard to the only case in which degeneration of cystic mastitis was demonstrated, it is emphasized that this incidence is not greater than that of spontaneous transformation of this definitely precancerous lesion. Routine treatment with testosterone is dangerous in suspected cases because it may elicit an endocrine response and may stimulate a latent malignant process.

*Streptomycin in Treatment of Pulmonary Tuberculosis. A. Reginster. —p. 401.
Pulmonary Silicosis and its Diagnosis. A. Thomas.—p. 426.

**Streptomycin in Pulmonary Tuberculosis.**—Reginster treated 8 tuberculous patients, 6 men between the ages of 23 and 51 and two girls aged 15 and 18 respectively, with streptomycin. One to 1.5 Gm. of the drug in two fractional doses was injected daily for ninety days. Pulmonary cavities represent lesions least favorably influenced by streptomycin. They furnish the most favorable medium in vivo for the development of resistance of Koch's bacillus to streptomycin. Treatment with streptomycin is indicated in acute or subacute miliary, pneumonic or bronchopneumonic lesions in the absence of ulcerations, and for ulcerative, vegetative or ulcerovegetative lesions of the upper respiratory passages. A patient who belongs to one of these two groups but who in addition presents a cavity should not be treated with streptomycin except where an effective collapse can be realized before the end of the first month; i. e., the period for which according to the author's experience resistance of the bacilli to streptomycin may be delayed. Patients amenable to surgical collapse therapy may be treated preoperatively and postoperatively with streptomycin. On palliative and experimental grounds it seems justified to practice a twenty-one day streptomycin course of treatment in patients with grave lesions of the upper respiratory passages who also present pulmonary lesions not accessible to collapse therapy or who already have been submitted to an ineffective collapse. These indications should not be considered definite, since the place of streptomycin in the treatment of pulmonary tuberculosis will be established only by strictly controlled therapeutic trials in long series of fairly homogeneous cases.

*Symptomatology of Pleural Endothelioma (Mesothelioma). K. Kaiser. —p. 189.
"Azygos Lobe" and Collapse Therapy; Tomographic and Endoscopic Exploration of Superior Mediastinal Recessus. R. Jeanneret, G. de Rahm, F. de Kovats Jr., and others.—p. 212.
Statistical Contribution to Tuberculosis of Kidneys. H. U. Gloor and G. Jaccard.—p. 232.

**Pleural Endothelioma.**—Kaiser reports 10 cases of endothelioma of the pleura in 5 men and 5 women between the ages of 37 and 71 years. The initial symptoms consisted of pain in the sacral region, in the hip and in the inguinal region, radiating to the shoulder, and of severe irritative cough. Three patients had stinging pain in the chest. The most important clinical sign was the rapid development of a hemorrhagic pleural exudate which had a decided tendency to recurrence. The burden placed on the pulmonary circulation caused right ventricular hypertrophy and dilatation which were demonstrated by corresponding alterations in the electrocardiogram. There was pronounced dyspnea. Secondary hypochromic anemia occurred regularly. The blood showed an important increase in sedimentation rate and a shift to the left of Weltmann's coagulation reaction. Death resulted within four to six months. Bronchoscopy may be an aid in the differential diagnosis from endobronchial tumor. Diagnosis can be established by pleuroscopy with simultaneous exploratory excision. In 1 case the diagnosis was carried out by thoracotomy. This should be practiced if less radical methods of diagnostic examination fail. There is no effective causal treatment. Symptomatic treatment requires daily aspiration of the fluid from the pleural cavity.

*Extirpation of Spleen Supporting Treatment with Penicillin for Bacterial Endocarditis. K. Fellinger.—p. 509.
Contribution to Criticism of Diagnosis of Appendicitis. G. Hennig. —p. 510.
Osteolysis Due to Squamous Celled Epithelioma. E. Morvay.—p. 512.
*Experimental Contribution to Problems of Differential Diagnosis in Connection with BCG Vaccination. S. Zimányi.—p. 515.

**Splenectomy in Bacterial Endocarditis.**—Fellinger treated 1 man aged 28 with bacterial endocarditis with 320,000 units of penicillin daily for six weeks. There was a rapid improvement in the general condition and in the tachycardia. Five months later rise in temperature and tachycardia were noted. A mild diastolic murmur over the aorta became accentuated, and peripheral signs of aortic insufficiency were manifest. The spleen was considerably enlarged. Twenty million units of penicillin were administered in six weeks, and the temperature was restored to normal. A new bout of fever occurred within a few days after the drug was discontinued. The spleen was considered as the focus of the infection and splenectomy was performed. Twelve million units of penicillin combined with sulfathiazole were administered postoperatively; the temperature returned to normal within two weeks. Culture from the spleen yielded Streptococcus viridans. The preoperative drop in the temperature resulting from penicillin suggests that the streptococci on the valves and in the blood were sensitive to penicillin. The secondary development of resistance of the streptococci in the spleen seems likely. The recovery after splenectomy demonstrated that failure of penicillin does not depend on the presence of deep ulceration of the valves, but that bacteria in the spleen, which are not accessible to penicillin, may be the carriers of the infection. Splenectomy is to be considered in every case of penicillin-resistant or recurrent bacterial endocarditis.

**Problems of Differential Diagnosis Connected with BCG Vaccination.**—According to Zimányi, the wide employment of BCG vaccination makes difficult the evaluation of the tuberculin test and of the diagnosis based on this test, since a positive reaction can take place after the injection of tuberculin after the vaccination. It is, nevertheless, indispensable to differentiate between the harmless infection which follows the BCG vaccination and a possible reinfection with its grave consequences. In Russia it has become a routine to produce Pirquet's reaction in addition to Mantoux's reaction three months after the vaccination; they consider the case as one of reinfection when both reactions to tests are positive. The correctness of this method was tested in 360 vaccinated children. With both tests performed simultaneously in 180 children, 153 (86 per cent) showed a positive Mantoux reaction and 89 (52.8 per cent) a positive Pirquet reaction. In a second group of 180 children Pirquet's reaction was produced first and Mantoux's test was performed two weeks later. The reaction to Mantoux's test was again positive in 153 children (86 per cent), while Pirquet's reaction was positive in only 10 children. The children in both groups had been vaccinated five months before the tests. No pathologic changes were demonstrated by the sedimentation rate or by roentgenologic examination in all 360 children. Mantoux's and Pirquet's tests, provided they are performed at the right time and in the right order, may be used as a basis for differential diagnosis, because a positive Pirquet reaction after BCG vaccination is not an equivalent of a reinfection and because a negative Mantoux reaction and even more a negative Pirquet reaction do not exclude a serious reinfection. A confirmation of the diagnosis in children with a positive Mantoux reaction and a negative Pirquet reaction may be obtained only by simultaneous determination of the blood sedimentation rate and roentgenologic examination. Additional examinations of the sputum and of the contents of the stomach may be carried out occasionally.

### 60:525-540 (Aug. 20) 1948. Partial Index

*Treatment of Tuberculosis of Skin With Vitamin $D_2$. G. Riehl.—p. 525.
Treatment of Acute Poisoning from Soporifics. H. Kofler.—p. 530.
Surgical Treatment of Panaritium: Results. W. Köle.—p. 531.
Value of Microscopic Examination of Mucosa of Uterus for Diagnosis of Extra-Uterine Pregnancy. H. Husslein.—p. 534.

**Vitamin $D_2$ in Tuberculosis of Skin.**—Riehl treated 150 patients with lupus vulgaris with vitamin $D_2$. Only 50 of these patients, 30 women and 20 men, have been followed long enough to be reported—24 of these have been treated for six to nine months and the remaining 26 for more than four months. Ten patients were given the French preparation "sterogyl," 3 ampules with 600,000 units each in one-half glass of water daily after each meal for the first week; 2 ampules daily for the second, third and fourth week, and then 1 ampule weekly for several months up to one year. Forty patients were given the British preparation calciferol ("glaxo"), in two weekly doses of 600,000 units, by intramuscular route. All the other patients were given the Swiss preparation "vi-dé." The duration of the disease was more than four decades in some of the patients, more than ten years in the majority and one to two years in a few. There was rapid healing of ulcerations which had resisted all other methods of treatment. Large ulcers healed within three to four weeks with a firm but fine scar, ulcers the size of a penny healed even more rapidly. There was rapid epithelization of the obstinate ulcers of the mucosa. A pronounced line of demarcation was obtained within two weeks in ulcerous destructive processes at the tip of the nose, septum and alae nasi, which prevented disintegration. Plane foci of lupus were the slowest in responding. Healing of foci of the pinna was slower than of those of the face. Infiltrates under the scars often were demonstrated on microscopic examination of patients with clinical recovery. There was increase in body weight up to 3 Kg. in three to four months. Appetite was increased. The blood calcium level showed a tendency to rise up to 14 mg. per hundred cubic centimeters and more. There were no signs of intoxication. Blood pressure showed a tendency to drop. Mantoux's test was performed every two weeks; a strongly positive reaction suggested a high allergy and warranted a good response. There was temporary swelling of regional lymph nodes and occasionally universal swelling of subcutaneous lymph nodes for twenty-four hours. Vitamin $D_2$ therapy proved to be definitely more effective and in a shorter time than all methods of treatment practiced before, except for the total excision of a focus, which may be feasible in rare cases only. The danger of intoxication may be prevented by repeated examination of blood pressure, body weight, blood sedimentation rate, differential blood count, Mantoux's test, roentgenologic control and determination of the blood calcium level. The patients must be admitted to the hospital for treatment and must remain there for several months.

# Book Notices

**Standards for the Diagnosis and Treatment of Cancer.** By the Cancer Committee of the Iowa State Medical Society. Second edition. Boards. Price, $1. Pp. 160. Athens Press, Iowa City, Iowa; A. W. Erskine, M.D., Secretary of the Cancer Committee of the Iowa State Medical Society, 326 Higley Bldg., Cedar Rapids, Iowa, 1948.

This is an excellent manual for the general practitioner dealing with the technic involved in the recognition of cancer by the family doctor who sees the majority of cancer patients first. This manual quite properly starts out with a consideration of the place of the family doctor in cancer control. It then proceeds to a detailed discussion of the various forms of cancer and the technics employed in their recognition. It has a brief chapter on radiation therapy and a fairly extensive bibliography on cancer arranged according to the source of the malignancy. This is the kind of postgraduate education which will help to keep the family physician, the general practitioner, functioning at highest efficiency.

**The Principles and Practice of Modern Cosmetics. Volume II: Cosmetic Materials: Their Origin, Characteristics, Uses and Dermatological Action.** By *Ralph G. Harry, F.R.I.C., Head of the Cosmetic* Department, Beecham Research Laboratories Ltd. Cloth. Price, 35s. Pp. 479, with 7 illustrations. Leonard Hill, Ltd., 17 Stratford Place, London, W. 1, 1948.

This book presents in alphabetical arrangement a list of materials commonly used in cosmetics or for cosmetic manufacture. Included are discussions on the origin, characteristics, uses and dermatologic action of cosmetic materials. Thus one may pass from "abracols" to zinc sulfate and find information on formula, molecular weight, occurrence or manufacture, physical and chemical properties, B. P. standard, use in toilet preparations and dermatologic action. The appendixes include discussions of methods of U. S. Toilet Goods Association for testing for certain substances and a list of the coal tar colors certified by the Food and Drug Administration. Although the book is written in England, it, unlike many others, has equal usefulness for those who reside outside the United Kingdom. Thus, this volume should be of considerable usefulness to those in the United States who are interested in the preparation or identification of cosmetics and cosmetic ingredients. It is not intended for the practitioner, but it will be found practical for the pharmacist, chemist, teacher and others who have interest in the details of cosmetology.

**Methods of Vitamin Assay.** Prepared and edited by The Association of Vitamin Chemists, Inc. Cloth. Price, $3.50. Pp. 189, with illustrations. Published for the The Association of Vitamin Chemists, Inc., by Interscience Publishers, Inc., 215 Fourth Ave., New York 3, 1947.

This book, prepared by a group of vitamin chemists, presents in detail satisfactory procedures and methods of assay available for vitamins A, D, C, $B_1$ $B_2$ and nicotinic acid and carotene. There is a reference list to the literature on the other vitamins and vitamin-like substances, and further revisions are promised to include assay methods for these. Wherever applicable, the microbiologic, chemical and physical methods of assay are described in detail. Each method explains the principle of the assay, the laboratory apparatus required, the preparation of the reagents and the detailed procedure followed by comments. There is also a general description of the vitamins, including their chemical and physical properties. An informative chapter on sampling for vitamin analyses is included for various types of food products, pharmaceuticals and biologic fluids. The use of check samples in the control of vitamin methods is specified in another chapter. This book will be useful for reference in any laboratory or industry interested in the field of vitamin assay methods.

**Occupational Therapy Source Book.** Edited by Sidney Licht, M.D. With an introduction by C. Charles Burlingame, M.D., Psychiatrist-in-Chief, The Institute of Living, Hartford, Connecticut. [Reprinted from Occupational Therapy and Rehabilitation 1947, 1948.] Cloth. Price, $1. Pp. 90. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1948.

In this small monograph Dr. Licht presents a clear outline of the early history of occupational therapy. He then documents fundamental psychiatric studies relating to occupational therapy which were first presented by Pinel in 1801 with other quotations from the writings of Reil, Halloran, Rush, Tuke, Esquirol, Leuret, Voisin, Kirkbride and Eva Charlotte Reid. This book will be of particular interest to institutional personnel and represents an excellent choice of contributors and their contributions to this subject.

**Bilharzial Cancer: Radiological Diagnosis and Treatment.** By Mahmoud Ahmed Afifi, M.B., Ch.B., M.R.C.S. Cloth. Price, 16s. Pp. 111, with 60 illustrations. H. K. Lewis & Co., Ltd., 136 Gower St., London, W.C. 1, 1948.

This small but fascinating book presents data from Egypt on the incidence of bilharziasis and cancer in various organs, ably discusses the roentgenologic diagnosis of bilharzial cancer and suggests the treatment of bilharzially associated cancer. It is of interest chiefly to urologists and radiologists. The evidence for an etiologic relationship between bilharziasis and cancer is, at the present time, of a statistical nature, which is inconclusive. The author shows a high coincidence of these two diseases in cancer of the bladder, prostate and colon. Unfortunately no data are presented giving the incidence of bilharziasis in these organs in nonneoplastic lesions, such as benign prostatic hypertrophy, and in routine autopsies. Other organs, such as lung, gallbladder, liver and pancreas, showed much bilharziasis but little cancer. This book, well written and interesting as it is, leaves many more questions unanswered than it settles. It left the reviewer frustrated because of its failure to give data which were probably at hand on control normal and pathologic tissues. The potential contributions of the statistical method have not yet been fully realized and the experimental approach has hardly been touched. It is hoped that the author will, in a few years, present a greatly expanded monograph on this subject.

**Die funktionelle Organisation des vegetativen Nervensystems.** Von W. R. Hess, o.ö. Professor der Physiologie an der Universität Zürich, Zürich. Cloth. Price, 18.50 Swiss francs. Pp. 226, with 80 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; Benno Schwabe, Klosterberg 27, Basel 10, 1948.

W. R. Hess, who recently summarized his work on the diencephalic centers of the autonomic nervous system (*Helv. physiol. Acta*, supplement IV and V, 1947/1948), gives a penetrating study of autonomic organization in the present work, which is recommended to any one who is interested not only in the knowledge of pertinent facts but in the interpretation of these data from the point of view of an organismically oriented physiology. Autonomic functions show different levels of organization. Adaptive reactions are noticeable even in peripheral autonomically innervated structures, but only at higher levels (spinal, medullary and diencephalic) are complex organ systems integrated. Cortically induced autonomic functions are largely related to the expression of emotion, whereas the subcortical centers of the autonomic nervous system coordinate vegetative functions such as regulation of body temperature. Study of the book is rather difficult because of the style, but it is definitely rewarding. Print and illustrations are excellent. The literature (about 250 numbers) is arranged alphabetically, while the papers referred to in the text are numbered consecutively. This is definitely inferior to the customary methods of citation and reference.

**Highlights of the National Conference on Family Life, Washington, D. C., May 5-8, 1948.** Paper. Price, 15 cents. Pp. 22. National Conference on Family Life, 10 E. 40th St., New York 16, [n.d.].

This is a pamphlet giving a brief summary of the proceedings of the National Conference on Family Life held in Washington, D. C., May 5 through 8, 1948. It consists mainly of the suggestions and recommendations arrived at by the Conference. Minority and divergent ideas are found in the footnotes. The Conference arrived at more or less obvious conclusions relating to the needs of individual family members in their community relationships. It called for more activities to draw the father back into active family membership and suggested the provision of more opportunities for the participation of young persons in community activities. The emphasis seemed to be on strengthening the family, but there is evidence in this report of a trend of thinking all too common at this time, namely, the "strengthening" of the family by coordinating it into more community activities, which tend to deemphasize the family and exalt the *community*.

**Hetero-Specific Alteration Therapy: A New Treatment for Pulmonary Tuberculosis Based on Specific Cellular Alteration Produced by a Mixed Autolysate of Typhoid Bacilli and Gonococci.** By Susumu Nukada, M.D., Ph.D., and Chieko Ryu, M.D. Paper. Pp. 80, with 5 illustrations. Japan Medical Publications Co., Ltd., Tokyo & Kyoto, 1948.

In 1924 (*J. Exper. Med.* 40:661) Nukada and Matsuzaki reported that the resistance of the heart of animals vaccinated with a certain kind of heterobacteria was greater than that of nonvaccinated control animals. Subsequently, Nukada and his collaborators studied the fluctuations in the resistance or defensive power against bacterial infection of animals following vaccination (immunization) with different varieties of heterobacteria to note which produced the best protection. They found a mixture of typhoid bacilli and gonococci produced the best "antitubercular" resistance. During the period 1931 to 1937 Nukada and Ryu determined the minimal doses required to affect the course of experimental tuberculosis in rabbits and guinea pigs given large amounts of virulent human tubercle bacilli intravenously. Most of the treated animals survived longer than controls or those treated with coli or pneumococcus vaccine. An attempt was made to isolate the active principle, and an "antitubercular" resistance in guinea pigs was produced by a mixture of "autolysate" (autodigestion product) of typhoid bacilli and gonococci ("heterosate"). The authors feel that the results produced by "heterosate" are due to an increased resistance or defensive power against the tubercle bacilli developed as a "specific alteration" in the tissue cells. Tests were made on tuberculous patients, and improvement similar to that noted in animals resulted particularly as pertained to reducing temperature.

The book is printed in English and presents tabulations of numerous experiments submitted in evidence. Although the data might be accepted as observations, it may be questioned whether the conclusions warrant clinical therapeutic application. Scientifically, there are wide gaps in the reasoning applied to justifying therapeutic conclusions. The "heterosate" prepared from heat-killed (53 C. for one hour) organisms and containing carbolic acid can hardly be called an autolysate. There is also some confusion as to its analysis as a preventive or therapeutic agent. Preventive tests proved a lesser incidence of tuberculosis in nurses (44 persons) and therapeutic use in 932 cases of pulmonary tuberculosis with "very satisfactory" results. It is proposed to call this method of treatment for pulmonary tuberculosis "hetero-specific alteration therapy" or "heterosate therapy," based on the conception of the production of a cellular alteration whereby the resisting or defensive power of the tissue cells is increased specifically against tubercle bacilli. The book should be read critically by those interested in tuberculosis.

**Midwifery.** By Ten Teachers under the direction of Clifford White, M.D., B.S., F.R.C.P. Edited by Clifford White, Frank Cook and William Gilliatt. Eighth edition. Cloth. Price, $6. Pp. 560, with 217 illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1948.

"Midwifery" shows a definite improvement in this edition. Illustrations are distinct and reproduced well. It is a clear and easily read volume.

The illustration on page 114, "Care of the Perineum," deviates considerably from the technic used in the better maternity clinics in this country. Danger of contamination of the right hand by the anus is evident. The inability to expose and protect the vulva properly by this method of delivery is self evident. Reference to episiotomy indicates a practice somewhat different from that encountered in the United States.

The discussion and management of vomiting due to pregnancy per se seems to fall a little short in completeness although there are over six pages in this section. Dieckmann has demonstrated that with proper treatment there is rarely if ever an indication for interruption because of vomiting of pregnancy, which varies from the implication of the discussion. Treatment of eclampsia seems a little incomplete.

The management of septic abortion is brief; yet indications are clearly given for the various recommended procedures. Value of penicillin is inadequately emphasized. There is a failure to point out the limited but possible value of streptomycin. Under treatment of repeated abortions the statement, "The condition is not associated with infertility," seems inaccurate because obviously repeated abortion does result in inability to conceive and carry through to viability.

The discussion of episiotomy on page 447 may not be appropriate for the student and does not rise to the level of the resident. Other suggestions of a similar nature could be submitted. The elimination of biography and much needless discourse (too often present in the best books in the United States) on the history of prior therapies is most commendable.

This book is recommended because of the direct approach, clear and adequate illustrations and the elimination of unessentials.

**A Textbook of Pharmacology and Therapeutics.** By Harold N. Wright, M.S., Ph.D., Associate Professor of Pharmacology, University of Minnesota, Minneapolis, and Mildred Montag, R.N., M.A., Director, Adelphi College School of Nursing, Garden City, N. Y. Fourth edition. Cloth. Price, $4. Pp. 720, with 95 illustrations. W. B. Saunders Co., 218 W. Washington Sq., Philadelphia 5, 1948.

This is the fourth edition of a book that is rather comprehensive in scope, perhaps too comprehensive for students of nursing. On the other hand, it is not sufficiently complete for medical students or pharmacists. The book, however, is apparently intended for nurses and probably contains all the information on drugs that is needed for this objective. Since it is intended to present pharmacology and therapeutics, one wonders about the need for discussing, for example, the physiology and pathology of the circulatory system. This would seem best left for other books which are written to present such topics. However, this is a fault not uncommonly found in many volumes; there seems to be a tendency for books undergoing revision to increase in content, with much of the increase being somewhat irrelevant material if the original perspective of the book is kept in view. But how much criticism should be directed against this is questionable, as students often appreciate accessory information that has a bearing on the subject which they are studying. One of the useful features of this book is the list of exercises included at the end of each chapter. These exercises pose some pertinent questions and should do much to fix the contents of the chapters in the minds of the readers. Obviously, the present book has had some considerable success or it would not have reached a fourth edition.

**Psychiatry for Everyman.** By J. A. C. Brown, M.B., Ch.B. Cloth. Price, $3. Pp. 247. The Philosophical Library, Inc., 15 E. 40th St., New York 16, 1947.

This simply written, short, comprehensive survey of the more outstanding contributions of psychiatry to the increasing understanding of mental and emotional illness, and of human behavior in general, recommends itself as a welcome addition to those books which can add measurably to the fundamental knowledge of "every man.". Although written primarily for the layman, it remains a scientific, authoritative review of the more outstanding contributions in this field of medicine. Extremely readable, it avoids the inaccuracies of many books which attempt to popularize medical themes. It will prove useful also to the medical student who wishes a concise survey of the field covered in his basic instruction in psychiatry, and will be welcomed by the social worker and the educator.

In the hands of the general public this book should help dispel much of the mysterious fear which exists concerning things psychiatric, while at the same time it discloses how the growing application of this accumulating knowledge, when more universally applied, will contribute immeasurably to the prevention of much human unhappiness.

**Racial Variations in Immunity to Syphilis: A Study of the Disease in the Chinese, White, and Negro Races.** By Chester North Frazier and Li Hung-Chiung. Cloth. Price, $2.50. Pp. 122, with 13 illustrations. University of Chicago Press, 5750 Ellis Ave., Chicago 37, 1948.

This monograph, based on an enormous experience with 16,845 consecutive cases of syphilis in the Chinese, white and Negro races, deals with the fundamental problem of immunity in syphilis.

The senior author has had a unique opportunity to observe the varying course of syphilis among these three different races in two first class syphilologic centers, that of the Johns Hopkins Hospital and the School of Hygiene and Public Health, and the Peiping Union Medical College. The junior author was formerly Director of Venereal Disease Control, National

Health Administration of China. The study was carried out over a period of more than twenty-five years. While the book is written in a rather philosophic tone, the statistical summations of the experience are impressive, and should satisfy the requirements of readers who wish to examine the data in detail.

Scattered studies of race and sex differences in the frequency with which late serious manifestations of syphilis occur have been made. In many instances, the studies have been based on such highly selected small groups of patients as to make the conclusions uncertain or downright impressionistic.

Frazier and Hung-Chiung submit clear evidence that syphilis in both Chinese males and females tends to become latent in a much higher portion of patients than in white and Negro males and females. The Chinese male has almost as good a chance of proceeding to latency in regard to a syphilitic infection as does the white female, in whom the infection is most benign for reasons which have only been guessed at. Early in the disease, acute periostitis and acute meningitis tend to develop much more frequently in the Chinese male than in the white. In spite of the tendency to meningeal involvement early in the disease, tertiary localization in Chinese was preponderantly extraneural.

The authors consider various backgrounds which might contribute to the benign course in the Chinese people, without coming to any definite conclusions. They reject the theory that special strains of spirochetes may cause localization of syphilis in the nervous system.

This short monograph will be of the greatest interest to syphilologists, in particular those who are struggling with the several unsolved fundamental problems in regard to the disease, and to any one interested in the peculiarities of reaction of man to chronic infectious diseases in general. It is highly recommended.

**Health Teaching in Schools for Teachers in Elementary and Secondary Schools.** By Ruth E. Grout, M.P.H., Ph.D., Associate Professor, School of Public Health and the College of Education, University of Minnesota, Minneapolis. Cloth. Price, $4. Pp. 320, with 18 illustrations. W. B. Saunders Co., 218 W. Washington Square, Philadelphia 5, 1948.

This is a book of primary interest to teachers and school administrators. As such, it can be recommended without reservation. It is prepared by a recognized authority, with assistance and collaboration from many competent advisers. It has as basic chapters the nature of health education in school and community; the health needs of the growing child; home, school and community health needs; educational principles and procedures, and planning for health education within the school. From this point the author proceeds to present guides to health teaching in elementary schools and in secondary schools. There is an excellent chapter on audiovisual materials and a good chapter on evaluation of progress in health education. A chapter is devoted to co-workers, that is, professional official and voluntary health agencies, and their cooperative role in health education. In the appendix is a rich list of general references, sources of free and inexpensive health education materials, a check sheet on school sanitation, a check sheet on the health content of courses in University High School (University of Minnesota) and a sample unit on alcohol, tobacco and narcotic drugs.

The book is well organized and is specific as well as comprehensive, telling exactly what to do and how to do it in definite situations. It is attractively made with a photogravure cover rendered washable. It is adequately indexed and well illustrated. Its interest to the physician lies in the fact that he is often called on for advice with regard to curriculum materials and health teaching guides. He cannot do better than recommend Dr. Grout's book.

**Your Diet for Longer Life.** By James A. Tobey, Dr.P.H., LL.D. Cloth. Price, $3.50. Pp. 280. Wilfred Funk, Inc., 227 E. 44th St., New York 17, 1948.

Doctor Tobey has applied his recognized capability for lively and interesting writing to the presentation in popular form of the well known and essentially uninteresting material about diet. The book completely describes the essential facts about food in their relationship to longer and better life, reducing, putting on weight, diet and reproduction, better teeth, dieting for personal beauty, the truth about acidosis, vitamins and all the other lures which health educators have endeavored to employ in the almost hopeless task of making people eat as they should instead of as they wish. It is a good manual for reference and is as readable as such a book can be expected to be. It is scientifically accurate and may be recommended by physicians to patients who want more information than is usually contained in the practicing physician's dietary listings.

**Therapy Through Interview.** By Stanley G. Law, M.D. Cloth. Price, $4.50. Pp. 313. McGraw-Hill Book Co., Inc., 330 W. 42nd St., New York 18, 1948.

Dr. Law has written an extremely interesting book. He has obviously combined a rather good knowledge of dynamic psychology with great intuition and a real interest in psychosomatic medicine. The casual reader may get the impression that psychotherapy is a rather simple procedure even though the author did not intend to convey this impression. Also, one may suspect that he is led more by intuition than by sound scientific knowledge. These are, however, minor criticisms and do not detract from the book's value. Certainly if the tremendous need for psychotherapy, particularly in the treatment of psychogenic symptoms, is to be anywhere near satisfied, approaches such as outlined in this book must be learned and utilized. The book is well worth reading by every physician regardless of specialization.

**X-Ray Diffraction Studies in Biology and Medicine.** By Mona Spiegel-Adolf, M.D., Professor of Colloid Chemistry and Head of the Department of Colloid Chemistry, Temple University School of Medicine, Philadelphia, and George C. Henny, M.S., M.D., Professor of Medical Physics and Head of the Department of Physics, Temple University School of Medicine. Cloth. Price, $5.50. Pp. 215, with 86 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1947.

This book is the first comprehensive survey on roentgen ray diffraction studies in biology and medicine. The information gathered by the authors indicates that the true amorphous state is rarely encountered and that many biologic materials such as muscles and nerves, which might be expected to show complete randomness of structure, yield roentgen ray diffraction patterns indicative of systematic arrangement. Valuable information on carbohydrates, amino acids and their derivatives, proteins, nucleoproteins, lipids, steroids, bones, teeth and concretions is revealed by the diffraction studies of the authors and others. A large bibliography is included.

Mathematical treatment is held to a minimum.

**Elsevier's Encyclopædia of Organic Chemistry.** Edited by E. Josephy and F. Radt. Volume 13: Tricyclic Compounds. Series III, Carboisocyclic Condensed Compounds. Cloth. Subscription Price, $78; Serial Price, $91; Volume Price, $104. Pp. 1265. Elsevier Publishing Co., Inc., 215 Fourth Ave., New York 3, 1946.

Volume 14, the first of this 20 volume series to be published, was reviewed in THE JOURNAL, Aug. 23, 1947, page 1515. A general description of the purpose and plan of the proposed series appeared in this review.

Volume 13 covers the chemical and physical properties, occurrence, synthesis and preparation, purification and reactions of the tricyclic organic compounds. Fluorene, acenaphthene, anthracene, phenanthrene and their ketone, alcohol and quinone structures and numerous derivatives are considered in detail. The rest of this book is concerned with lesser known tricyclic compounds.

**The Hospital Care of Neurosurgical Patients.** By Wallace B. Hamby, M.D., F.A.C.S., Professor of Neurology and Neurological Surgery, University of Buffalo School of Medicine, Buffalo, New York. Second *edition.* Cloth. Price, $3. Pp. 156, with 30 illustrations. Charles C Thomas, 301-327 East Lawrence Ave., Springfield, Illinois, 1948.

This useful text, now in its second edition, has met with popular approval from house officers, general practitioners and nurses since its first edition. Its chief value is the clear and concise way in which the author presents the problems of the neurosurgeon as encountered in hospital practice. The author has covered the field with care, so that a general knowledge of this highly specialized field results from a careful reading of the book. In view of the increasing importance of neurologic surgery, it is a great boon to young men entering internships and to nurses interested in surgery and postoperative care.

# Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

## MYOPATHIES

*To the Editor:*—What are the cause, etiology, symptoms, types and medical treatment of (1) muscular progressive myopathic atrophy, (2) muscular progressive myelopathic atrophy and (3) muscular progressive neuritic atrophies?

M.D., New Jersey.

Answer.—The terms used to designate the various syndromes and diseases with muscular weakness and atrophy as the primary signs are not as yet clearly defined in neurologic literature. The hereditary, familial and congenital aspects, however, of many of the muscular dystrophies and myopathies allow for broad groupings under these terms. Perhaps the simplest classification, and that most widely adopted, is the one used by Aring and Cobb in 1935. These authors used the term "primary" muscular atrophies to designate one large class, with subheadings of sporadic and familial diseases. The commonest clinical types of sporadic primary muscular atrophies are progressive muscular atrophy, including bulbar paralysis, and amyotrophic lateral sclerosis. In this group also is classed amyotonia congenita, a disease the cause of which appears to be a lack of development of muscle fibers, although there may be some changes in the Betz cells of the corticospinal tract.

Most of the other muscular atrophies are familial in type and, in turn, are divided into two groups; first, the myopathic diseases, in which the histopathologic changes, if any, are limited to the muscles themselves or to the endocrine glands, and the second group of strongly inherited diseases which have muscular atrophies usually secondary to changes in the cells of the spinal cord. The latter class, called myelopathic diseases, are true system diseases.

1. *Muscular Progressive Myopathic Atrophy.*—It is presumed that this term refers to the so-called myopathies, of which the principal ones are myasthenia gravis, family periodic paralysis, progressive muscular dystrophy, myotonia congenita and dystrophia myotonica. The etiology, in the strict sense of the word, is not known of any one of these diseases. In myasthenia gravis, however, the disease is presumed by most investigators to be due to a disorder of the chemical constituents at the myoneural junction, primarily the cholinesterase and the acetylcholine. The symptoms and medical treatment of this disorder have been extensively investigated by Viets and others, who have outlined the modern treatment with neostigmine. Family periodic paralysis, a hereditary disease, is associated with low levels of potassium in the blood serum. Attacks can be terminated by the oral administration of potassium chloride, as pointed out by Talbott and others. Little is known about the etiology and treatment of progressive muscular dystrophy. The disease occurs in many forms, but medicine is not much beyond the descriptive stage of the clinical state in the elucidation of the problems associated with the dystrophies in general. At present a recognized, effective treatment is not available. Vitamins have not been of distinct therapeutic value. Myotonia congenita, or Thomsen's disease, a hereditary condition usually occurring in childhood and persisting through life without much evidence of muscular atrophy, has been shown to respond to treatment with quinine. Thomasen's recent monograph has brought our knowledge of this disease up to date.

2. *Muscular Progressive Myelopathic Atrophy.*—The chief diseases in this group are infantile muscular atrophy, hypertrophic neuritis, peroneal muscular atrophy, Friedreich's ataxia and one or two other similar conditions. The pathology of these diseases gives evidence of close relationship. All are system diseases, with changes in the central nervous system. In hypertrophic neuritis there are additional conspicuous lesions outside of the central nervous system in the nerve trunks. In some instances hypertrophic neuritis may be associated with congenital optic atrophy and with other myelopathic syndromes. There are many subvarieties. Cobb believes that we should classify them under a general heading of familial system diseases of the neuraxis. Their etiology is unknown, and there is no specific treatment for any one of them. As in many of the other muscular atrophies, extensive clinical observations have been made, and their symptom complex is well recognized.

3. *Muscular Progressive Neuritic Atrophies.*—These have been referred to under 2.

The fullest discussion of the whole group is contained in the chapter on spinomuscular and muscular diseases in Wilson's "Neurology," although the classification used is somewhat different from and a little more complicated than the one used by Aring and Cobb.

## PENICILLIN AND FUNGICIDES

*To the Editor:*—Is penicillin locally helpful in the treatment of mycoses?

L. Edward Giovine, M.D., Woodside, N. Y.

Answer.—Penicillin is entirely useless in the local treatment of superficial fungus infections in man. Most pathogenic strains or species of the dermatophytes have been tested in vitro and proved to be resistant to penicillin in concentrations of 500 or more units per cc. (Fleming, R. S., and Queen, F. B.: Penicillin Resistance. II Of Fungi, *Am. J. Clin. Path.*, **16**:66, 1946).

Pathogenic dermatophytes themselves produce substances resembling penicillin (Peck, S. M., and Hewitt, W. L.: Production of Antibiotic Substance Similar to Penicillin by Pathogenic Fungi (Dermatophytes), *Pub. Health Rep.* **60**:148, 1945), although they have incomparably less bactericidal effect. That there is some relation between penicillin and antigens produced by dermatophytes is substantiated in clinical experience by the frequent appearance of "dermatophytids" (localized or generalized allergic eruptions) following systemic administration of penicillin in patients who are carriers of dermatophytes. This reaction is similar to that following the injection of dermatophyte vaccines in allergic individuals.

Theoretically it might seem useful to add penicillin to fungicidal preparations for the purpose of combating secondary bacterial infection which often accompanies fungus infections. However, the local application of penicillin carries with it the danger of cutaneous or general sensitization. This danger is so serious that warnings have been issued against the indiscriminate local application of penicillin to the skin surface (see, for instance, Sulzberger, M. B., and Baer, R. L.: Year Book of Dermatology and Syphilology, Chicago, Year Book Publishers, 1946, p. 12). Unnecessary local application may cause sensitization of such degree that later, when penicillin might be vital, its systemic administration is precluded. For combating secondary bacterial infection in dermatomycoses the traditional though less potent bactericides such as ammoniated mercury are entirely satisfactory. Their use leads less often to sensitization, and its consequences, if it occurs, are less serious.

## PARENTERAL QUINIDINE

*To the Editor:*—Is there a preparation of quinidine which may be injected hypodermically or intramuscularly?

Dr. Tom Spies, in his monograph, "Rehabilitation Through Better Nutrition," in figure 20, exhibits a reduction in the size of a patient's dilated heart following the use of thiamine. Have such satisfactory effects been reported following the use of nicotinic acid, nicotinamide or coramine?

M.D., Montana.

Answer.—The report of Sturnick, Riseman and Sagall (The Journal, March 20, 1943, p. 917) includes directions for the sterilization and ampuling of a parenteral solution of quinidine hydrochloride prepared according to the following formula:

| | Gm. or Cc. |
|---|---|
| Quinidine hydrochloride ........................ | 15 |
| Antipyrine ........................................ | 15 |
| Urea .................................................. | 20 |
| Distilled water ..........................to make | 100 |

*The Bulletin of the American Society of Hospital Pharmacists* has indicated that a "small number of 10 cc. ampules of quinidine lactate with 0.65 Gm. per ampule may be obtained for experimental use by cardiologists if they write directly to Dr. Kenneth Kohlstaedt, Medical Department, Eli Lilly and Company, Indianapolis, Indiana." The recent report of Katz (The Journal, April 17, 1948, p. 1028) includes information on parenteral use of quinidine, but mention is not made of a commercial source of supply.

The illustration in the Spies monograph to which the correspondent refers relates to a case of beriberi heart disease in which decrease in heart size followed parenteral thiamine therapy. Evidence that this particular manifestation of thiamine deficiency has been effectively treated with nicotinic acid, nicotinamide, or nikethamide ("coramine") is lacking. Cardiac dilatation reported in this case was due to a specific vitamin deficiency. Evidence that cardiac dilatation from other causes will respond to thiamine or to any other vitamin is absent.

## CHRONIC URTICARIA

*To the Editor:—A male patient aged 44 has had recurrent hives since January 1948. Physical examination did not elicit abnormality except for a mild spasticity of the colon. The patient was hospitalized and given large doses of diphenhydramine hydrochloride intravenously for about one week with some improvement. He was sent home with the instructions that he should take 4 to 8 (50 mg.) capsules of diphenhydramine hydrochloride a day as needed for the hives. After six months of medication with this drug he came to me for further treatment. Skin tests for food allergy revealed strong positive reactions to yeast, chicken, lamb, shrimp, trout, cheese, string beans, sugar cane and several other foods. I gave him a diet to follow, and have also given him calcium intravenously with some improvement. The hives bother him about 3 a. m. He feels hungry all the time, and it seems that when he eats to satisfy himself he is more apt to have the hives. I also gave him thyroid, 1 grain (60 mg.), daily. A dermatologist suggested that he spend three weeks away from home. He did this, but while he was away he became worse. This patient has been cooperative, but after seven months of the hives he is becoming impatient. He is somewhat nervous, but he takes phenobarbital when he needs it. Is there anything else that I might do for him? I have tried him on the other new drugs such as tripelennamine hydrochloride and "thephorin" (2-methyl-9-phenyl-1, 3, 4, 9-tetrahydroindeno [2.1-C] pyridine) without avail.*

*M.D., Colorado.*

ANSWER.—Chronic urticaria usually can be traced to one of the following: drugs, foci of infection, foods or psychogenic factors. Less often physical agents such as heat, cold, light rays or exercise; endocrine abnormalities; or external agents, such as insect bites, vapors or dust, may initiate an attack. It seems that almost any abnormality may be the underlying source of chronic urticaria, even slight dermatophytosis. Therefore, it is essential that a painstaking and searching history be taken on the chance that it may reveal absorption of a chemical from an unusual source such as from toothpaste, nose drops or cosmetics.

Skin tests, unless expertly performed, are apt to give misleading results when performed on a skin subject to urticarial lesions. When foods are suspected, they sometimes can be identified by means of a diet-elimination regimen in which the patient, after having water only for one day, gradually adds a simple foodstuff to the diet, one thing at each meal. An accurate diet record should be kept. One should first examine the patient carefully for hidden foci of infection and other abnormalities, even to the point of examining catheterized specimens of urine, prostatic smears, roentgenograms of the sinus cavities and the cholecystic system. The patient should be observed in the meantime and questioned repeatedly for evidence that might establish a psychogenic origin. Throughout the investigative phase, he should receive no drugs. Later, if necessary, one may cautiously prescribe antihistaminic preparations or ephedrine sulfate, ⅜ grain (25 mg.) four times daily, and empirically mercury with chalk, and perhaps cholagogues, laxatives and mild sedatives.

## COLLAPSE THERAPY

*To the Editor:—With use of "lucite" plumbage in pulmonary tuberculosis collapse therapy have there been reports of "lucite" irritation as a cause of carcinomatous lesions? Are there other reported complications from use of "lucite" in pulmonary collapse therapy?*

*M.D., Nebraska.*

ANSWER.—In pulmonary tuberculosis the use of "lucite balls" and paraffin (surgical) in an operation known as extrapleural pneumonlysis does not cause malignant lesions. The surgeon who used "lucite balls" first, stopped after the 26th operation because they traveled. Surgical paraffin, however, acts as a firm mold and fills any contour of collapse. Both paraffin and lucite are foreign bodies. Any pleural space can receive paraffin, but in one with a thin pleura "lucite balls" are contraindicated since they will tear tissue and allow the balls to migrate. In any operation for tuberculosis the biggest complication is tuberculosis.

## RAGWEED IN HONOLULU

*To the Editor:—What is the giant rag weed situation in Honolulu?*

*Lester Neuman, M.D., Washington, D. C.*

ANSWER.—Giant ragweed plants do not grow in Honolulu or in any part of the Hawaiian Islands. Common ragweed is found in a restricted prairie area south of Waimea (Kamuela) on the northern part of the Island of Hawaii. The prevailing northeast winds cannot possibly carry the relatively small amount of pollen from these weeds to any city or village on Hawaii or any of the other islands of the group. False ragweed (Franseria strigulosa) is a common roadside plant from Pearl Harbor northward to Haleiwa and along the north shore of the Island of Oahu. The total acreage of these weeds is comparatively small and the prevailing northeast winds carry the pollen away from Honolulu rather than toward the city. Atmospheric pollen tests made by a local allergist over a period of eleven months did not reveal a single grain of ragweed pollen.

## MONGOLISM

*To the Editor:—Please send information regarding infants with mongolism. What can be done for this condition?*

*W. E. Lewis, M.D., Kansas City, Mo.*

ANSWER.—Ingalls has published a detailed study of the pathogenesis and etiology of mongolism in the *American Journal of Diseases of Children* of March and August 1947. No specific treatment is known to be effective in the amelioration of the syndrome. Numerous attempts at endocrine therapy have met with indifferent results. Any teaching hospital, "top flight" clinic, certified pediatrician or experienced general practitioner should be able to make the diagnosis during the first year of life. Often it can be made at birth on the basis of the characteristic physiognomy, brachycephaly and frequently associated stigmata such as dwarfed middle phalanx of the fifth finger, congenital heart disease, malformed ears and other malformations.

Placement is highly advisable (Aldrich, C. A.: *Am. J. Ment. Deficiency,* **52:**127, 1947), in order to allow other or future children a normal home. A child with mongolism will adapt happily, quickly and permanently to a custodial environment. Placement is the kindest thing which can be done to the afflicted person and is so obviously indicated from both the parents' and society's point of view that the only single contrary argument is sentiment so divorced from reality that it is closer to sentimentality.

A ray of hope exists—not of cure, but of prevention. All epidemiologic evidence points to maternal factors as the cause of mongolism. Repetition of the disease in the same family is so rare that the risk is ordinarily no contraindication to future pregnancy. A complete checkup of the mother's health is first indicated, with positive measures to remedy any chronic, systemic, endocrine or gynecologic disorder.

## COMBINATION OF ANTIBIOTICS

*To the Editor:—Is there a contraindication to the combined use of penicillin, streptomycin and sulfadiazine? Can penicillin and streptomycin be combined in the same isotonic sodium chloride solution and given together? Can morphine or codeine be added to this solution, thereby eliminating additional annoyance to the patient?*

*Glenn T. Howard, M.D., Pearsall, Texas.*

ANSWER.—Combined use of penicillin, streptomycin and sulfadiazine is permissible. Although the spectrum of activity of each of these is different, they are frequently used in combination in treating mixed bacterial infections. Penicillin and streptomycin may be given together in the same syringe. Solutions containing the two antibiotics should not be kept for more than a few hours, since the acid salts of streptomycin may tend to inactivate the basic salts of penicillin. This would not occur rapidly, so that such mixtures would probably be stable for several hours.

Although reports of the effects of mixtures of morphine or codeine and the antibiotics are not available, these narcotics are marketed as acid salts; there is therefore a possibility of pharmaceutic incompatibility with penicillin. Before preparing such mixtures, one should make a study of possible incompatibility. If not incompatible the drugs could be combined extemporaneously in a single injection.

## LESIONS OF FRONTAL AND PONTINE AREAS

*To the Editor:—What are the diagnostic signs in the eye which would distinguish a lesion in the frontal lobe from one in the pons if both produce paralysis of lateral gaze?*

*M.D., North Dakota.*

ANSWER.—The most characteristic, but uncommon, ocular sign of a lesion of the frontal lobe is the so-called Foster-Kennedy syndrome: true retrobulbar neuritis with formation of a central scotoma and primary optic atrophy on the side of the lesion together with concomitant papilledema in the opposite eye. Nearly always depression or loss of the sense of smell is found on the side on which the retrobulbar neuritis has occurred.

The ocular sign most characteristic, and again uncommon, of pontine tumors is paralysis of the sixth nerve on one side with an opposite-sided hemiplegia combined with inability to move the eyes conjugately to the side of the lesion (Foville's syndrome).

Paralysis of lateral conjugate movements may occur with hemispheric or pontine lesions, and unless the lesions are bilateral the paralysis is likely to be transient. The differential diagnosis is discussed by Bielschowsky (Paralysis of the Conjugate Ocular Movements of the Eyes, *Arch. Ophth.* **13:**569, 1935) and Walsh (Clinical Neuro-Ophthalmology, Baltimore, Williams & Wilkins, 1947, pp. 123, 296, 1143 and 1215).

## USE OF DIGITALIS IN PEDIATRICS

*To the Editor:*—What are methods, doses and drugs for rapid and slow digitilization in pediatric practice? What doses and methods of administration of quinidine are recommended for infants? I refer to supraventricular tachycardia. M.D., Massachusetts.

Answer.—Large doses of digitalis should not be given to patients with cardiac disease during the active, febrile stage of rheumatic fever or any other manifestation of rheumatic disease. Large doses may produce heart block or arrythmia.

Ordinarily, digitalis should be given by mouth, usually about 1½ grains (0.1 Gm.) once or twice daily. If nausea or slowing of the pulse should develop, digitalis should be discontinued for several days until symptoms of intoxication have disappeared. When difficulty occurs in the oral administration, the drug may be administered by rectum (15 to 30 minims [1 to 2 cc.] of the tincture diluted with 1 ounce [30 cc.] of water). When the pulse rate has been reduced, the dose should be diminished to 15 minims diluted with 1 ounce water, once or twice daily. The use of digitalis in pericarditis is dangerous. There are few if any indications for the use of quinidine in heart disorders of childhood. Auricular fibrillation is rare, and it is doubtful whether the administration of quinidine would help. The dose of the drug for children is usually stated as 1 to 1½ grains (60 to 100 mg.) two to three times daily, or in any given case the dose would be calculated on the basis of the age and weight of the child.

## KERATITIS SICCA

*To the Editor:*—A male patient, aged 69, has a negative history up to 1945; when glaucoma of both eyes was diagnosed. Two posterior sclerotomies (trephines) were done in each eye within a period of six months before the pressure remained normal. Throughout the period of treatment he has been given a host of drops to instil into his eyes. During the past year he has had an irritated right eye with sensations of burning, smarting, and photophobia relieved only when the eye is closed. Six ophthalmologists have made a diagnosis of chronic catarrhal conjunctivitis. Purulent discharge, excessive lacrimation and positive colors are absent. On gross inspection the conjunctiva *appears normal. Clinical examination* and all laboratory investigations have been negative. Treatment locally in addition to the many instillations, has included hot applications, cold applications and flushing with normal saline. General treatment has included sulfadiazine, penicillin, salicylates, antihistamines, and sedatives. The patient is a business man and the constant irritation is making a psychoneurotic of him. Please discuss this condition. M.D., New York.

Answer.—It is not likely that glaucoma nor the use of miotics is directly accountable for the irritation of the right eye. For two and one half years miotics have not been necessary and presumably not used. Other solutions instilled into the eyes have been used to arrest such sensations as burning, smarting and photophobia of one eye only. Evidently the symptoms are not evidences of drug sensitivity. In view of the negative cultures and the nearly normal appearance of the conjunctiva, there is little probability that the symptoms are caused by infection or malfunction of the lacrimal drainage apparatus, and it would seem that the eye has been subjected to unnecessary and unwarranted medication with antibacterial and antibiotic agents used without usual indications. The symptoms are those of insufficient lacrimyal secretion. Relief by closing the eye, protection from rapid drying of the cornea, is a common experience in keratitis sicca. Schirmer's test and slit lamp inspection of the corneal epithelium following staining with fluorescin solution may tell the story. If keratitis sicca is found, artificial tears containing his own blood serum will probably give the greatest and most prompt relief. In any event the instillation into the eye of medicinal solutions should be kept to a minimum and sedative ointments used only after patch tests have indicated lack of drug sensitivity.

## CIRCUMCISION

*To the Editor:*—What are indications for circumcisions? This type of surgery has become almost routine in this community, and the question has arisen as to its merit in newborn infants. What is the *attitude* of the American College of Pediatrics, and the American College of Surgery in this regard? S. R. Parkinson, M.D., Marysville, Calif.

Answer.—It is generally conceded that routine circumcision of the newborn is definitely indicated and should be done, not only for cleanliness of the genitalia, but also to prevent future phimosis, periphimosis and balanoposthitis. The American College of Surgeons does not give a definite opinion on this subject, and, as far as can be determined, neither does the American Society of Pediatrics.

## TASTE ABERRATION

*To the Editor:*—A patient, aged 42, has had a nauseating taste in her mouth for the past four years. She has the impression that this taste is worse when the saliva flows into the mouth. This offensive taste appeared shortly after having a cavity in her second right inferior molar cleaned and filled. She consulted me two years after having this dental attention. Prior to her visit she had had various medicinal treatments, as well as psychic therapy, all to no avail. I encouraged her to have the filling removed and a temporary one inserted for a few months, which was done, but without any relief. She had a slight nasal obstruction which was corrected and also a tonsillectomy, hoping to obtain some alleviation, but without result. I referred her to a specialist in gastrointestinal diseases, who was unable to help her. She was given potassium iodide, sulfanilamide and frequent application of silver nitrate (4 to 8 per cent) about the mouth. She has been tested for allergy and is sensitive to wheat, corn, and a few other foods, all of which have been omitted for one or two weeks at a time. Cosmetics have been omitted without benefit. Evidence of any pathologic condition is lacking. Please suggest treatment. M.D., *Ohio.*

Answer.—The four year stable persistence of the complaint, with the absence of an obvious local or regional lesion or infection, in a woman aged 42 years, with a failure to respond to the many therapeutic approaches, would suggest that the cause is psychoneurotic. A situational intolerance, the climacteric and hysteria may all include abnormalities of taste.

Taste aberrations may also result from secretions or accretions, from infections of the upper and the lower respiratory tract, from a fault in sensory reception, conveyance and interpretation, and from an association-memory cause. It is supposed, from the report, that the tongue, salivary glands, teeth, gums, breath, sinuses and lungs are normal; all of these may cause a disagreeable taste if they are abnormal, and should be checked again for certainty.

The three drugs which have been taken for therapy may themselves cause a "bad taste," as do numerous others. It should be certain that she is not using an unmentioned laxative, bromide, tonic, nasal solution or unusual diet ingredient, since some of them may be causative. The dentifrice or mouth wash which she uses should be investigated. Food particles, especially meat, may become foul in a few hours, and may be caught each day in the same spaces between teeth; this factor may be ruled out by regular use of dental floss and a refreshing, astringent zinc chloride mouth wash.

Since "flavor" is composed of both smell and taste elements, and since nausea was mentioned, a nasal cause should be sought. Glossitis, allergy and differences of electric potential are origins which seem to be excluded.

To decide whether the quantity or quality of saliva is of importance, two tests may be made. Give her (without describing its possible effect) a tablet (15 mg.) of neostigmine bromide after one or two meals; profuse watery saliva should result. A tablet of homatropine methylbromide may be given fifteen minutes before each of several meals; a decrease in saliva flow, as well as a gastric relaxation, should result.

If all these observations are of no help, obtain the impression of a good neuropsychiatrist. He can quickly check the taste areas of the tongue, exclude a remote uncinate cause, and probe the emotions for a functional origin.

## INCREASED LIBIDO OF MENOPAUSE

*To the Editor:*—A patient has complained of abnormal sex desire for the last two years. She is a white woman aged 45 years who has started the menopause syndrome. She did not have such symptoms until about the onset of menopause. What is the diagnosis and treatment of this case? M. K. Braly, M.D., Mooreland, Okla.

Answer.—Most women note a gradually decreasing sex desire following the onset of the menopause, although this factor varies with different women. Some few women note a decided increase in libido, sometimes accounted for by the absence of fear of pregnancy. Sometimes patients say that estrogens increase their sex desire. A thorough pelvic examination should be done to rule out hormone-producing tumors of the ovary. Occasionally androgens will decrease this disturbing symptom, but they should be used guardedly and not in sufficient quantities to masculinize the patient.

There is frequently a psychogenic condition underlying such phenomena, as the libido pattern is usually established before the onset of the menopause and it usually does not change greatly.

Other questions to be considered are: What are her sexual outlets (husband, family, children)? Is she frustrated? Are the talk of other women and her reading habits healthy? Psychotherapy plus small doses of phenobarbital and a busy schedule can frequently be combined to subdue the disturbing problem.

## CELIAC SYNDROME

To the Editor:—Please outline therapy for celiac syndrome excluding protein milk and banana flakes. What other foods can a child eat? Can the patient take diabetic foods, since they are low in carbohydrate content?

M.D., Massachusetts.

ANSWER.—The most important consideration in undertaking therapy of a child with celiac syndrome is correct diagnosis. Infants and children with celiac syndrome have distended abdomens, wasting and bulky foul stools. These symptoms may arise from a variety of causes including infection, absence of secretion from the pancreas as in fibrosis of the pancreas, disturbance of function of the bowel due to congenital abnormality of the intestine, parasitic infestation and a number of other disease states which will interfere with intestinal digestion. It may be assumed that the child has intestinal malabsorption for which no cause has been found and that an idiopathic intestinal insufficiency presumably due to faulty absorption by the intestinal mucosa itself exists. A careful search should have been made for all underlying conditions which could produce these symptoms.

Children with "celiac disease" or idiopathic intestinal malabsorption may ordinarily be easily managed by dietary therapy. Most severe forms can usually be successfully treated with ordinary skim milk, cottage cheese, lean meat and junket.

First give skim milk up to 8 ounces five times a day and add the other foods one at a time only as is required by increasing appetite. The diet should not be elaborated until the abdominal distention is receding, the stools have become more nearly normal and the child's appetite has improved. Infection requires immediate reduction of the diet to milk. Orange juice is usually tolerated. Any form of starchy carbohydrate food such as rice, potatoes, bread or pudding should be rigorously excluded from the diet until recovery is complete, often two or three years after the institution of treatment. Proceed cautiously with the simple foods enumerated and do not attempt too rapid progress and overtax the digestion of the child. If this principle is adhered to, a variety of simple foods are often tolerated, with the exception of starchy carbohydrates, which are the least tolerated of all. The items mentioned will provide ideal nutrition for a child, and there does not appear to be any advantage in diabetic foods which would compare unfavorably in nutritive content. Simple pureed vegetables would be the next item to be added when the foods listed have been well tolerated for a long period. No matter how poor the appetite, these things will be taken if offered in appropriate amounts and the diet adhered to in the face of the demanding and capricious appetite characteristic of these children during their difficult phase. Accessory food factors such as vitamin A, D, C and B complex should be provided in liberal amounts and are well tolerated in any acceptable preparation.

## PETROLEUM CARCINOGENICITY

To the Editor:—Are the following substances carcinogenic: (1) white petroleum jelly, (2) yellow petroleum jelly, (3) dark red veterinary petroleum jelly, (4) wool fat and (5) "aquaphor" (an ointment containing hydroxyl animal fats)?

A. F. Liber, M.D., Temple, Tex.

ANSWER.—It is not known that any of the five substances mentioned are carcinogenic, but neither can it be definitely stated that they are not. Under conditions of ordinary use, they are not recognized to have carcinogenic activity. Because of low intensity or delay in attaining full effects, such activity might, however, have been overlooked. No record of scientific tests is readily found except in the case of wool fat, which has been used as a vehicle for testing carcinogenic substances. Under certain conditions, it reduces their carcinogenicity. Petroleum jellies are obtained from petroleum. The chemical composition of crude petroleums varies greatly with their field of origin and so, apparently, does their carcinogenicity. The latter varies also with the subsequent treatment to which the products are subjected. Products derived from petroleums having a high content of polycyclic hydrocarbons and asphalts are theoretically most dangerous.

## ELECTRIC CONVULSIVE THERAPY

To the Editor:—With usual or modified electroshock treatment has damage to the optic nerve more than transitory irritation such as seeing colors and sparks been described?

Wladimir G. Eliasberg, M.D., New York.

ANSWER.—Neurologic complications following electric convulsive therapy are practically unknown. Even aggravation of previous neurologic conditions has not been observed. Patients taking "metrazol" (pentamethylenetetrazol) therapy report lightning flashes and streaks of fire before their eyes, but these sensations are avoided with the electroshock treatment. Subconjunctival hemorrhages are the only ocular complication reported resulting from electroshock therapy.

## SUDDEN DEATH IN INFANTS

To the Editor:—What are the usual pathologic findings in infants who die suddenly?

M.D., South Carolina.

ANSWER.—The pathologic findings in infants who die suddenly cannot be stated briefly. The causes of sudden death are probably numerous. The older assumption that sudden death was due to thymic enlargement, or the so-called status thymicolymphaticus, is no longer accepted. Some infants are smothered in bed by pillows or bedclothing. Occasionally, others are strangled by tapes, bands or cords becoming fastened about the neck. Others are asphyxiated by foreign bodies which become lodged in the trachea or bronchi. Sometimes the inhalation of fumes, acids or dusting powder causes asphyxiation. A common cause is the regurgitation of ingested food into the pharynx, followed by aspiration into the bronchi and lungs, causing suffocation and sudden death. Sometimes these patients die from an obscure and undiscovered visceral disorder. Pneumonia has been the cause of sudden death. Meningitis may be malignant and produce fatal outcome in young infants before the disease is recognized; the same is true in the case of foudroyant scarlet fever.

## CONTAMINATED WELLS

To the Editor:—The situation described in the query on "Contaminated Wells" (The Journal, Aug. 14, 1948) has occurred in slightly varying form on a number of occasions over the years. My colleagues and I have gathered the facts in a number of cases and have given such aid and advice as we could. The hazard to the owner of the well and the user of the water is not that of exposure to lead, but rather of the ingestion of gasoline. The use of drinking water even slightly contaminated with gasoline will result in chemical gastroenteritis, with varying degrees of acute irritation of the central nervous system. This syndrome will develop promptly and long before there would be any chance of absorbing lead in significant amounts, and the acute character of this type of illness, once it has been seen, is such as to impress on one, forcibly, the fact, so little recognized by physicians or laymen, that gasoline in the alimentary tract, as in other tissues of the body, is a dangerous material.

The fate of the tetraethyl lead in leaded gasoline that leaches into a well is somewhat variable with the circumstances. This lead compound, together with the dye in the gasoline, may be absorbed in the soil to such an extent that the original lead content of the gasoline is greatly reduced, perhaps to a negligible level. In any case, the lead compound, being insoluble in water, contaminates the water only to the extent of its presence in solution within the droplets of gasoline. The separation of the gasoline from the water automatically separates out the lead. Incidentally, the dose of lead which can be taken in by drinking water contaminated with leaded gasoline is negligible, as a little calculation will show. Tetraethyl lead rarely occurs in gasoline in concentrations in excess of 1 part in 1,260 parts by volume, and, even in high octane aeronautic fuels, the highest concentration is 1 part in 800. At this maximum concentration, the ingestion of 10 cc. of gasoline mixed into the water (a large, dangerous and highly distasteful dose) will result in the ingestion of but 12 mg. of lead. Such a dose of lead (as tetraethyl lead) would be wholly insignificant, unless repeated frequently, and frequent use of such water would be impossible because of the prompt and certain intervention of acute gasoline intoxication.

It is not practical, usually, to treat water from wells contaminated with gasoline (or petroleum) so as to make it potable. This can be done by letting the water stand until the gasoline separates, removing the separated gasoline and then filtering the remainder through activated charcoal. (Incidentally, these procedures will remove completely any tetraethyl lead which may be in the gasoline.) However, the means of accomplishing such filtration is inconvenient and expensive. It has been found possible, in several instances, to pump the water out of a well so completely and over such a period of time as to remove the contaminant from the seepage bed of the well, thereby restoring the well to its former state. Weeks or months of pumping out and discarding the water may be required, but it is well worth the trouble if the desired result can be obtained. Whether or not this procedure is feasible depends on establishing the source, and determining the probable quantity and spread, of the gasoline (or other petroleum product). The latter can usually be done through the cooperative efforts of the petroleum distributor or distributors whose products may be involved in suspicion.

## PRESBYOPIA

To the Editor:—I am writing to take exception to your answer concerning presbyopia in the July 24 issue of The Journal, page 1176, to the inquiry of W. Q. Wolfson, M.D., of Chicago.

The inquirer asks whether presbyopia is influenced by hormonal controls. The answer given is excellent but not complete. Nearly all ophthalmologists have encountered patients whose powers of accommodation have suddenly decreased beyond the expected. On questioning patients, especially women, it is found that they are usually getting large doses of ovarian hormone in some form or other. Also, when this therapy is discontinued the accommodative effort returns to that patient's normal. In addition, a similar evidence is frequent in young boys to whom testicular hormone is given with the idea in mind of aiding in the descent of a testicle. I know of no research work done on this problem, but a clinical paper has been written: Mayer, L. L.: Effect of Diethylstilbestrol on Accommodation. Arch. Ophth. 32:133, 1944.

# TREATMENT OF PRIMARY ATYPICAL NONBACTERIAL PNEUMONIA WITH AUREOMYCIN

EMANUEL B. SCHOENBACH, M.D.
and
MORTON S. BRYER, M.D.
Baltimore

Primary atypical nonbacterial pneumonia has been reported with increasing frequency during the past fifteen years.[1] This disease has since received particular attention. The intensive studies on disease of the respiratory tract conducted during World War II served to differentiate "primary atypical pneumonia" from similar pulmonary infections of established bacterial, viral or rickettsial causes.[2] Clinically, diseases caused by the viruses of influenza, psittacosis, ornithosis and the rickettsiae of Q fever resemble atypical pneumonia.[2] No causative agent has been isolated from patients suffering from this disease, although pooled sputum from patients has been shown to be capable of inciting the disease in human volunteers, even after it was passed through Corning sintered glass or Seitz filters.[3] At present, there is no specific laboratory procedure available for confirming the clinical diagnosis. It has been noted that cold hemagglutinins and agglutinins for Streptococcus MG often develop in the serum of patients during the course of this disease.[2b] The detection of these antibodies aids in the characterization of the disease, although their specific relationship to the pathogenesis of atypical pneumonia is unknown.

The diagnosis of primary atypical pneumonia is based chiefly on the following criteria:

1. The onset is usually gradual, with nonproductive cough, fever, headache, malaise, chilly sensations and occasionally substernal pain. The absence of initial chill, bloody sputum and abrupt onset aid in its differentiation from pneumococcic pneumonia.

2. Physical examination often reveals minimal signs in the chest which are out of proportion to the roentgen evidence of pulmonary consolidation.

3. Laboratory examinations usually show a low to normal leukocyte count. Pneumococci or other pathogenic organisms are frequently not isolated from sputum, throat or nasopharyngeal cultures or by mouse inoculations.

4. Serologic studies on serial serum specimens do not reveal the development of antibodies for recognized viral or rickettsial agents.

5. Treatment with sulfadiazine or penicillin is not associated with clinical or objective improvement in the uncomplicated case. Penicillin has been given in huge doses without influencing the course of the disease.

6. The appearance of cold hemagglutinins in the serum of patients for human group O cells or agglutinins for Streptococcus MG during the course of the disease or in convalescence has been noted in a variable proportion of cases in different series.

The diagnosis of primary atypical pneumonia is based on the history and signs of disease of the respiratory tract coupled with roentgen evidence of pulmonary involvement which cannot be associated with any of the known bacterial, viral or rickettsial agents of disease either by cultural or serologic study.

Recently, aureomycin, an antibiotic derived from cultures of Streptomyces aureofaciens,[4] has been shown to be an effective chemotherapeutic agent in various bacterial, rickettsial and viral infections of experimental animals and human beings.[5] The drug can be administered orally, is well tolerated and is relatively nontoxic. In the course of an extensive investigation to delimit the clinical application of aureomycin, it was noted that patients, ill with primary atypical nonbacterial pneumonia, manifested rapid defervescence and decided clinical improvement when treated with this drug.[5c] Further experience confirmed these earlier

Presented before the Eastern Section, American Federation for Clinical Research, Dec. 4, 1948.

From the Department of Preventive Medicine, Johns Hopkins University School of Medicine.

Aureomycin (duomycin®) was supplied by the Lederle Laboratories Division American Cyanamid Company.

This study was supported by a grant to the Department of Preventive Medicine, the Johns Hopkins University School of Medicine, from the Abbott Laboratories, Eli Lilly and Company, Lederle Laboratories Division American Cyanamid Company, Parke, Davis & Company and the Upjohn Company.

Dr. George S. Mirick, Department of Medicine, Johns Hopkins University School of Medicine; Dr. Thomas G. Ward, Department of Bacteriology, Johns Hopkins School of Hygiene and Public Health, and Dr. Herald R. Cox, Lederle Laboratories, carried out various serologic procedures which were of inestimable value in characterizing these cases.

observations, and, despite the indeterminate causation of the disease, it is felt that aureomycin is a valuable chemotherapeutic agent in this disease.

### OBSERVATIONS AND RESULTS

A group of 13 consecutive patients was treated orally with the hydrochloride salt of aureomycin. The significant clinical and laboratory data for these patients are summarized in tables 1 and 2. The dosage of aureomycin employed and the response to therapy are presented in table 3.

Eight of these patients were female, and 5 were male. Their age distribution ranged from 10 years to 59 years. Twelve of these patients were deemed severely, but not gravely, ill when aureomycin therapy was instituted. One patient had been ill without evident clinical improvement for several weeks before treatment was begun. He was only moderately ill at that time. All the patients were civilians, and all were hospitalized.

Aureomycin therapy was begun on the second to twenty-first day of illness. Ten of these patients had received penicillin and/or sulfadiazine without manifest improvement. All patients had experienced a severe to moderate hacking nonproductive cough, headache and chilly sensations. The fever, preceding aureomycin therapy, varied between 101 and 105.2 F. In 9 patients, the temperature before treatment was 104 F. or higher. Many of the patients complained of nausea, associated with abdominal pain in 1 patient and with diarrhea in another. Signs of pulmonary inflammation were absent to minimal in 4 cases on physical examination. In the remaining 9 cases, clearly defined evidence of pneumonia, with dulness to percussion, rales and abnormal breath sounds, was elicited. Roentgenograms of the chest showed definite areas of infiltration in all

cultures of nose or throat. Intraperitoneal inoculation of mice with sputum and nasopharyngeal blood broth cultures were negative for pneumococci in each case. Blood cultures taken before therapy were all sterile.

Serial specimens of serum were examined serologically.[6] They were tested for the antibodies associated with infection produced by influenza virus, psittacosis, Q fever, the agglutinins for Streptococcus MG and cold hemagglutinins. In 11 cases to date, repeated complement fixation tests with other rickettsial antigens (R. rickettsi R. mooseri, R. prowazeki and R. akari) were also performed, but all results were negative. The strains of influenza virus employed were types A (PR-8), B (Lee), A′ (Fort-Monmouth) and O-5 (type A isolated in Baltimore 1946 by Dr. Thomas G. Ward). None of the 13 patients examined showed a rise in influenza antibody titer as measured by the inhibition of red blood cell agglutination. All serums were negative for psittacosis, ornithosis and Q fever, as well as other rickettsial complement-fixing antibodies. Reactions to additional serologic tests, namely heterophil antibody and agglutinins for the enteric group, Brucella tularensis and Proteus $OX_{19}$ and $OX_2$, were negative.

The serologic data are summarized in table 2. In 6 of the 13 patients, high titers of cold hemagglutinins developed. Treatment with aureomycin in these cases was begun on the seventh to tenth day of disease, and the agglutinins appeared on the tenth to sixteenth day of illness. This proportion positive is similar to that noted for severely ill patients in other reported series.[7] Streptococcus MG agglutinations were positive (titer higher than 1:20) in 9 of 13 patients.

Only oral aureomycin was employed in this group of patients. An initial dose of 30 to 50 mg. of aureomycin per kilogram of body weight per day was employed. The usual schedule of drug administration consisted of a priming dose of 100 to 250 mg. every hour for three doses, followed by the same dosage of aureomycin every two hours until the patients become afebrile (rectal temperature 100 F. or less). Thereafter, the drug was given every four to six hours for two to five days (15 to 20 mg. per kilogram). Variation in this dosage schedule occurred when the drug was in poor supply. Patients treated on the second to twenty-first day of their illness became afebrile within twelve to seventy-two hours. Nine patients were afebrile within twenty-four hours after the institution of aureomycin therapy. Treatment was begun on the second to twenty-first day of illness (median sixth day). Three patients became afebrile within twenty-four to forty-eight hours, while 1 patient, with excellent clinical response, did not become afebrile until seventy-two hours after treatment. Treatment of these 4 patients was initiated on the second to ninth day of disease (median seventh day). The patient (M. C., case 4) who remained febrile for seventy-two hours after the institution of aureomycin therapy was extremely ill and cyanotic, and involvement of four lobes was noted on physical examination and in the roentgenogram of the chest.

Subjective clinical improvement coincided with lysis of the fever. The cough, however, persisted and improved only gradually. Weakness of varying degree was evident during convalescence. It was most pronounced in those patients in whom treatment was not instituted until the later days of disease. No patients relapsed after treatment with aureomycin was discontinued. One patient had an infection of the upper part of the respiratory tract with coryza, nasal congestion, and temperature readings to 101 F. one week after treatment had been discontinued. Roentgen examination revealed no evidence of pulmonary consolidation. A second patient while still under treatment had a low grade fever associated with a leukocye count up to 35,000 per cubic millimeter. He remained asymptomatic, and serial roentgenograms showed progressive resolution of the pulmonary lesions. Exhaustive study revealed no cause for the leukocytosis, which subsided during the next two weeks. It was believed that he had experienced venous thrombosis. His cold hemagglutinin titer became positive to a dilution of 1:512 coincident with this episode. No such hematologic response has been noted in over 80 patients or in 5 normal persons treated with aureomycin. A third patient presented evidence of mild bilateral femoral vein phlebitis without elevation of temperature on the twelfth day of disease. She had been afebrile for three days. Cold hemagglutinins, which had been normal two days previously, rose to 1:512 on the day that the venous tenderness was detected. In all other patients, convalescence was uneventful and serial roentgenograms showed progressive resolution.

## REPORT OF CASES

The following abstracts of the course of several representative patients are presented to illustrate this experience.

Case 3.—*F. K., a 31 year old white woman, became ill with* nonproductive cough, headache and fever. She experienced chilly sensations but no shaking chills. Her oral temperature varied between 100 and 103 F. with symptomatic and antipyretic therapy, which was employed for one day. During the next three days, crystalline penicillin G, 300,000 units daily, was administered intramuscularly without effect and her temperature remained elevated. A leukocyte count was 9,500 on the fourth day of illness. She was admitted to the Sinai Hospital, Baltimore, on the following day.

On admission, the patient appeared acutely ill, with temperature 104 F. (rectal), pulse rate 132 and paroxysmal nonproductive cough. Dulness to percussion and bronchovesicular breath sounds were heard over the right anterior side of the chest, and occasional crepitant rales were audible in this area. Tenderness of the right lower quadrant of the abdomen was noted, and the patient had vomited on one occasion.

Hematologic examination showed: hemoglobin 13.3 Gm. per hundred cubic centimeters and total leukocytes 9,900 per cubic millimeter, with a differential count of polymorphonuclear neutrophils 82 per cent, lymphocytes 16 per cent and monocytes 2 per cent. The corrected sedimentation rate was 41 mm. (Wintrobe). Repeated examinations of the urine of the chemical content of the blood and serologic tests showed normal results. Blood culture was sterile. Nose, throat and nasopharyngeal cultures showed only the presence of Streptococcus viridans and a few colonies of hemolytic Staph. aureus. No pneumococci were detected even by mouse inoculation. Results of roentgen examinations and specific agglutinations are presented in figure 1.

Aureomycin therapy was begun on the afternoon of the sixth day of disease, when her temperature was 104.2 F. (rectal). Within twenty-four hours, it had fallen progressively to 99.8 F.

---

[6] Influenza virus antibodies were determined by the technic of inhibition of red cell agglutination by Dr. Thomas G. Ward of the Department of Bacteriology, The Johns Hopkins University School of Hygiene and Public Health. Psittacosis and rickettsial complement fixation tests were performed by Dr. Herald R. Cox, of the Lederle Laboratories Division American Cyanamid Company. Dr. George S. Mirick of the Department of Medicine, The Johns Hopkins School of Medicine, tested the serums for Streptococcus MG agglutinins. Agglutination in a dilution of 1:20 was considered the upper limit found in normal serum with this latter antigen. Cold hemagglutinins were determined using human group O Rh negative fresh red blood cells in a final concentration of 0.3 per cent. These tests were run on two separate occasions, and no differences were noted. Mr. Abraham Prostic of the Sinai Hospital, Baltimore, assisted in these tests.

[7] Horsfall.[2b] *Morgan, H. R., and Finland, M.:* Serologic Findings in Patients with Primary Atypical Pneumonia, Am. J. Clin. Path. **18:** 593, 1948.

Symptomatic improvement was evident within twelve hours after therapy was begun. Aureomycin was administered for a total period of four days. Convalescence was uneventful, and the patient was discharged on the fourteenth day of her illness, four days after the aureomycin was discontinued. She was well except for mild paroxysms of coughing.

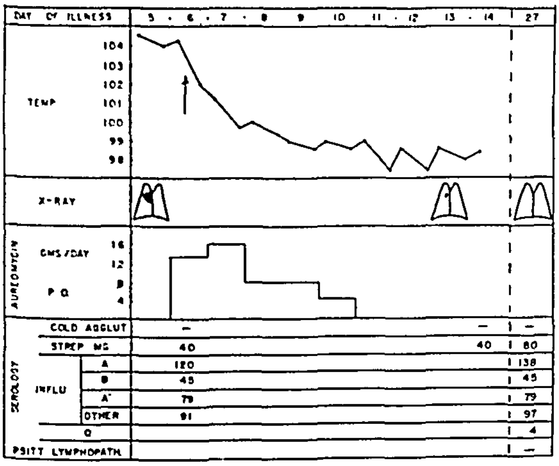

Fig. 1.—Chart of data in case 3 (F. K., female, age 31 years, weight 115 pounds [52 Kg.]).

Case 9.—B. B., a 41 year old white woman, had a paroxysmal nonproductive cough associated with temperature readings up to 101 F. Two days after onset her temperature rose to 104 F. and sulfonamide drug and penicillin therapy was instituted. The cough, headache and fever persisted, and the patient was referred to the Sinai Hospital, Baltimore, on the fourth day of illness.

On admission, the patient was acutely ill with a hacking nonproductive cough, temperature 103 F. (rectal), pulse rate 100 and respirations 28. Impaired breath sounds and slight dulness to percussion were noted at the left lung base. The total leukocyte count was 6,500, with the following differential count: polymorphonuclear neutrophils 76 per cent, lymphocytes 17 per cent and monocytes 7 per cent. Results of examination of the urine, stool and chemical content of the blood were normal.

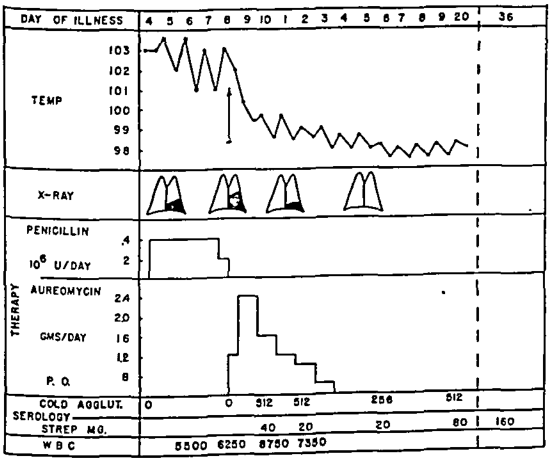

Fig. 2.—Chart of data in case 9 (B. B., female, age 41 years, weight 128 pounds [58 Kg.]).

She was treated with penicillin, 400,000 units daily for three and one-half days, but her daily temperature persisted at 103 to 103.6 F. On the afternoon of the eighth day of illness, aureomycin therapy was instituted. Within twenty-four hours the temperature had fallen to 99.4 F. (rectal), and she remained afebrile. Her course and pertinent laboratory studies are presented in figure 2.

Case 11.—I. R., a 43 year old white woman, had had intimate contact ten to nineteen days before her illness with her sister (B. B., case 9). She became ill with headache, nonproductive cough, chilly sensations and temperature reading of 104 F. (oral). The fever and cough persisted despite penicillin therapy, 100,000 units every four hours, plus caronamide for three days. She was admitted to the Sinai Hospital, Baltimore, on the fourth day of her illness.

On admission, she was acutely ill. Her temperature was 103 F. and pulse rate 92. She was not cyanotic. Dulness and diminished tactile fremitus were noted in the left lung base posteriorly. Breath sounds were somewhat diminished in this region. The total leukocyte count was 6,050, with a differential distribution of polymorphonuclear neutrophils 86 per cent, lymphocytes 9 per cent and monocytes 5 per cent. Sedimentation rate was 40 mm. corrected (Wintrobe). Blood culture was sterile and nasopharyngeal and throat cultures showed only Neisseria. Mouse inoculation was negative for pneumococci. Results of examination of the urine, stool and chemical content of the blood were normal. Results of roentgen examinations and pertinent laboratory data are presented in figure 3.

Despite the lack of response to penicillin and the known exposure to primary atypical pneumonia, further trial of penicillin was deemed indicated. She received 400,000 units of penicillin G intramuscularly daily for three days without evidence of subjective or objective improvement. Oral aureomycin therapy was begun on the afternoon of the seventh day of illness, and her temperature was normal on the following day. Convalescence was uneventful. Treatment was discontinued after five days, and she was discharged as well six days later.

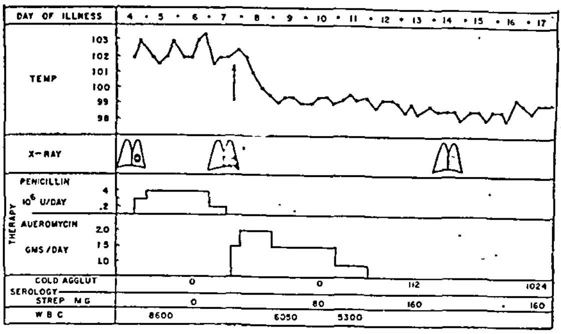

Fig. 3.—Chart of data in case 11 (I. R., female, age 43 years, weight 136½ pounds [62 Kg.]).

## COMMENT

Primary atypical pneumonia is a disease of the respiratory tract which can be differentiated from many similar clinical entities only by exclusion. In this series of patients bacteriologic examinations did not disclose any of the organisms usually associated with bacterial pneumonia. Serologic studies did not confirm influenza virus, psittacosis-lymphogranuloma virus, or the rickettsiae of Q fever, spotted fever, typhus or rickettsialpox as causative factors. Significant cold hemagglutinin titers and agglutination of Streptococcus MG were obtained in 46 per cent and 69 per cent, respectively, of these cases. The titers obtained with these two tests have varied significantly in different series. It has also been apparent that the proportion of positive titers and the proportion of patients found with positive reactions to these tests can be correlated with the severity and duration of the disease. The effect of chemotherapy, with the resultant rapid arrest of the disease, on the development of these agglutinins has not been ascertained. Cabasso and Cox have demonstrated that when embryonated hen's eggs are infected with mumps virus and treated with 2.0 mg. of aureomycin twenty-four hours thereafter, the virus proliferates but does not exhibit red blood cell agglutination. Subinoculation of untreated eggs yields virus with characteristic hemagglutinive properties.[8]

The 13 consecutive patients ill with primary atypical pneumonia who were treated with aureomycin have manifested a striking clinical response. The great variation in the clinical course of patients ill with primary atypical pneumonia of unknown cause is well understood. It should be emphasized, however, that all but 1 of the patients in this group were severely ill and all required hospitalization. This group differs in its composition from the reported series of cases among military personnel, of which only a small proportion was considered severely ill. The possibility, that the prompt response to treatment observed in each patient of this unselected consecutive series was purely fortuitous appears remote. Nine of these patients had received penicillin and/or sulfadiazine in dosages usually deemed adequate, without any apparent response. Prompt clinical improvement was noted soon after therapy with aureomycin was instituted. No inherent antipyretic effect has been observed with this antibiotic in typhoid or certain other febrile diseases.[9]

The amount of aureomycin used and its schedule of administration were empirically determined as a result of previous experience with the treatment of numerous types of infections. The drug was well tolerated. Nausea, which was present in 6 of these 13 cases prior to therapy, did not interfere with the oral dosage schedule. With the amount of aureomycin used in this series, nausea abated on treatment and was not noted in the other patients. In the treatment of other infections, when larger doses were given for more prolonged periods, nausea and anorexia attributable to aureomycin were encountered. This reaction was usually decidedly alleviated by use of aluminum hydroxide preparations. Several of the patients in this series complained of mild drowsiness. No neurologic abnormalities, nystagmus, vertigo, tinnitus or auditory disturbances were observed. The 1 patient who had transient fever and leukocytosis while receiving treatment has already been described. No similar reaction has been noted in over 80 patients treated with aureomycin, and at present it appears unlikely that this complication can be attributed to the drug.

The observations in these 13 patients would indicate that aureomycin is an effective chemotherapeutic agent for the treatment of primary atypical nonbacterial pneumonia.

### SUMMARY

Thirteen patients with primary atypical nonbacterial pneumonia were treated with aureomycin. The results have been sufficiently encouraging to indicate that this drug is an effective chemotherapeutic agent for this disease. No specific causative agent could be demonstrated for this series of cases of primary atypical pneumonia. Cold hemagglutinins were present in 46 per cent of this series, and agglutinins for a strain of Streptococcus MG were demonstrated in 69 per cent of the cases.

### ADDENDUM

A total of 18 completely studied patients have been treated to date (Jan. 5, 1949). Cold hemagglutinins were present in 50 per cent and agglutination for Streptococcus MG was positive in 75 per cent of these patients. Other studies have not indicated any specific cause. The response of these patients has been similar to that of the patients reported herein.

# MANAGEMENT OF OCCIPUT POSTERIOR POSITION

GERALD W. GUSTAFSON, M.D.
Indianapolis

In the past twenty years, the literature on the management of the occiput posterior position has been voluminous and varied. The problem is still worthy of study, as any one practicing clinical obstetrics will agree. This presentation is based on private patients personally delivered by me for the years 1942-1947 inclusive and cared for in three Indianapolis hospitals, namely, St. Vincent's Hospital, Methodist Hospital and the Coleman Hospital of the Indiana University Medical Center.

All posterior positions may be divided into three groups as far as management is concerned: First, the largest group, constituting about 70 per cent of the total, in which rotation will occur spontaneously after engagement, with comparative ease in delivery, either spontaneously or with low or mid forceps. The only problem associated with this group is that of making it as large as possible by conservative handling of the entire group. Secondly, there is a small group of cases associated usually with enough pelvic contraction or disproportion so that even after hours of labor engagement does not occur; there is then persistent nonengagement of the head. Some of these may be classified with the first group after the second stage is reached; some will be of the third group, and in some abdominal delivery will be necessary, not because of the posterior position but because of disproportion. The third group consists of those cases in which engagement occurs but there is failure of rotation. These are the cases of so-called persistent occiput posterior position. It is in the handling of these cases that there is the greatest difference in opinion, and this is the group that I particularly wish to discuss. The size of this group will vary in different reports, depending on whether the author is radical or conservative regarding the length of the second stage of labor. Those of the former point of view advocate interference at the very beginning of the second stage, before there has been sufficient time for spontaneous rotation, while those of the latter wait for varying degrees of time in the second stage before interference, thus decreasing the number of patients requiring operative interference or assistance and lowering the station when it is necessary.

The type of operative interference also varies considerably in different communities and in different clinics, as well as with the skill of the operator. For instance, a patient with a persistent occiput posterior in New York is apt to be delivered with the Barton forceps. However, in Jersey City, N. J., she would likely be delivered by means of the Kielland forceps. If, however, she were in Buffalo, a version and extraction would be in order. Moving westward to Cleveland, she would either have a version and extraction or a Bill's modified Scanzoni maneuver. In Chicago, she would be treated by manual rotation or the key-in-lock maneuver.

### CAUSATION

The pelvis itself is of great importance in the occurrence of posterior position. Many times, the position occurs in borderline pelves, especially of the android

---

Read before the Section on Obstetrics and Gynecology at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 23, 1948.

type with narrow fore pelvis, or in pelves with inlet, midplane or outlet contraction, and, because of this, dystocia may be present. As Cosgrove[1] has pointed out, in these cases the primary problem is an evaluation of the asymmetry of the pelvis or the degree of cephalopelvic disproportion involved.

Many years before the birth of roentgenologic pelvimetry, the staff of the old Chicago Lying-in Hospital had recognized the high incidence of posterior position in a particular type of person, with an android pelvis. These persons are short and stocky and have short long bones, a wide symphysis, spade hands and girdle obesity. Horner[2] drew attention to them, and DeLee gave the name of dystrophia dystocia syndrome. Cornell[3] and Greenhill[4] have described their labors and emphasized the high incidence of associated posterior positions. Since then, Caldwell and Moloy[5] have shown the high incidence of posterior position in the android pelvis by means of their roentgenologic studies, while Thoms,[6] also, has pointed out the occurrence in the transversely contracted or anthropoid type of pelvis. While the incidence is highest in the android and anthropoid, it also occurs in the flat or platypelloid pelvis and in normal pelves.

In recent years, more traumatic pelves are seen as the result of automobile accidents. Some of these will show pronounced asymmetry and resultant occiput posterior positions. To consider the occiput posterior as a clinical entity and that alone as the cause of dystocia in these cases would be obviously fallacious and often disastrous.

In addition to variations in pelvic architecture, which D'Esopo[7] stated are responsible for about 90 per cent of cases of primary posterior position, other causes are anything that will prevent rotation of the head, either mechanical, such as prolapsed arm or fibroids, or deficient uterine activity. The angle of fetal axis toward the inlet and increased pelvic inclination are also considered factors.

## INCIDENCE

In 28,494 cases of labor, Stander[8] reported an incidence of 8.1 per cent cases of posterior position. Danforth[9] studied 1,565 private patients over a nine year period, examined early in labor, and found the incidence to be 27.1 per cent, the right posterior being observed 6.7 times more frequently than the left. Calkins[10] reported an incidence of posterior position approaching that of anterior.

It is difficult to obtain an accurate incidence of posterior position, because many of the patients enter the hospital in advanced labor, examinations are usually abdominal and rectal and often the first examination is done by the intern. Because of this, I have not attempted to find the total number of our cases, as it would have been inaccurate. However, in each case of persistent posterior position the patient was carefully examined before delivery vaginally, and this number is accurate.

*Persistent Occiput Posterior Position.*—Cosgrove reported an incidence of 7.6 per cent, having 366 persistent posterior positions in 4,810 private cases. Danforth reported 143 cases of persistent posterior position in 1,565 deliveries, or 131 in the cases with vaginal delivery. Recently, Miles[11] listed 594 cases of persistent posterior position in a series of 2,601 private cases, an incidence of 22.4 per cent.

In this series, there were 106 cases of persistent posterior position in 2,922 deliveries, an incidence of 3.6 per cent. Of these cases, there were 72 instances of right posterior and 34 of left posterior position. In all, there was engagement of the head but failure to rotate. In addition, there were 17 patients during this interval for whom cesarean section was done when the occiput was in the posterior position and the head not engaged. These I would classify in group 2 or with persistent nonengagement of the head.

TABLE 1.—*Cases of Persistent Occiput Posterior Position*

| Year | No. of Deliveries | Persistent Occiput Posterior Position |
|---|---|---|
| 1942 | 415 | 12 |
| 1943 | 442 | 21 |
| 1944 | 428 | 10 |
| 1945 | 537 | 21 |
| 1946 | 553 | 20 |
| 1947 | 547 | 22 |
| Total | 2,922 | 106 (3.6%) |

## POSTERIOR POSITION IN PREGNANCY

During the last month of pregnancy, primary occiput posterior position is found when the head is felt over the inlet with the occiput palpated deep posteriorly and the cephalic prominence anteriorly on the opposite side. Either the back is palpated far over on one side or there may be difficulty in palpating the back, as, in some instances, the baby's back will almost coincide with the back of the mother, making the small parts of the baby directly in the midline or felt on both sides anteriorly. There may be a distinct groove seen transversely across the lower part of the abdomen, similar to that present when there is a full bladder or when there is threatened rupture of the uterus. Location of the fetal heart may vary. If it is on the same side as the fetal back, it is usually out to the flank, but in case of deflexion, the baby's chest is thrust forward and the fetal heart may be heard loudest on the side opposite the back.

After diagnosis has been made, and certainly if there is any possibility of pelvic contraction, measurements should be checked with roentgen pelvimetry. By seeing the patient first walk in, one can usually identify the pelvis of the dystrophia dystocia syndrome.

Pregnancy itself is apt to be prolonged, these patients often going two or more weeks past the estimated day of delivery. While I may occasionally attempt to start labor with a dose of castor oil followed with a hot enema, it is my policy not to induce labor mechanically unless the pelvis is ample, the head engaged and the indication definite.

### CHARACTER OF LABOR

Labor in persistent posterior positon is generally slower and longer, especially in those cases in which there are firm cervices and poor labor pains. In 20 of the 106 cases there was prolonged labor, i. e., labor more than twenty-four hours. In 6 of these cases, there was *a preliminary stage characterized by irregular pain* without actual effacement and dilatation, but accompanied with enough pain to exhaust the patient. Obviously, if this occurs, the patient must have rest, and often sedation is followed by much stronger pains which accomplish work. Rupture of the bag of waters is often early. The head stays high longer than in anterior position, and there is less flexion. The head may enter the pelvis in the transverse diameter and then rotate to the posterior, or it may have been in primary posterior position and entered in one of the oblique diameters with the occiput posterior. The occiput may rotate to the hollow of the sacrum, or it may rotate to the anterior only to stop as a deep transverse arrest. In 1 of the patients, a 36 year old primigravida, after twenty-eight hours of first stage labor and one hour of second stage, the head descended and spontaneous rotation occurred, enabling delivery to take place by low forceps and, thus, putting her in our first group rather than in the third group. Rotation may not occur until the head is on the pelvic floor, but *may occur any time after the spines* have been reached or at station 0. In occipitosacral position, spontaneous delivery may occur, and, if so, it does by one of two mechanisms. The first is one with flexion; the region just anterior to the large fontanel or the forehead stems under the symphysis, and the occiput goes either through or over the perineum. The second mechanism is with the base of the nose under the pubis, the forehead taking the lead much as in cases of brow presentation.

TABLE 2.—*Parity of Patients Having Persistent Occiput Posterior Position in the Three Hospitals*

| | Hospital | | | |
|---|---|---|---|---|
| Parity | St. Vincent's | Methodist | Coleman | Total |
| P I | 18 | 27 | 25 | 70 |
| P II | 8 | 9 | 6 | 23 |
| P III | 4 | 3 | 0 | 7 |
| P IV | 2 | 4 | 0 | 6 |

### MANAGEMENT

Calkins has done much to alleviate fear of the posterior position by showing that the position in itself *should be regarded* as a normal one and labor so treated, provided that the condition of mother and baby remains good and there is continued progress.

Thirty out of 70 primiparas with persistent posterior position showed nonengaged heads at the first examination during labor. Diagnosis of disproportion is more difficult with the occiput posterior position, and, unless the pelvis is highly contracted, a trial of labor should be given. If the head remains high, it is wise again to check the pelvis and, if it has not been done previously, to make a roentgen pelvimetric examination. It is often helpful, but the ordinary roentgenogram gives little information. If the pelvis seems adequate, then the treatment is one of watchful expectancy.

Station correctly diagnosed is just as important as dilatation; yet, in the various reports on posterior position, one seldom is given the exact station of the presenting part, so that it is often impossible to tell whether operative procedures are done when the head is engaged or when it is still unengaged. I employ the station as suggested by DeLee[12] whenever the lower portion of the head, exclusive of the caput, is at the level of the ischial spines, the station is 0 and engagement has just occurred. Because of excessive molding and long caput, it is possible for the caput to be in the midpelvis and with the biparietal diameter of the head above the brim. Inaccurate diagnosis of station is, I am sure, one of the reasons for failure of forceps operations, when they should never have been attempted in the first place. It is true that at —1 station one may drag the baby's head into the pelvis with success, but good obstetrics dictates the use of the forceps only after engagement has occurred. Stations of all these persistent posterior heads are given in table 3, and these are the stations at which the patients were first seen in the hospital early in labor.

Sedation during the first stage is imperative. For the patient having the first baby, there is no better sedative than morphine. During the war years, most patients were given pentobarbital sodium (nembutal®), 6 grains (0.4 Gm.) and this was supplemented as needed with ether given rectally. Recently I have been using more meperidine hydrochloride with scopolamine hydrobromide. Recently Hingson and others[13] *listed* among the dangers and limitations of continuous caudal analgesia the increased incidence of occipitoposterior position. If mother and baby remain in good condition, there *must not be interference in the first stage.* To attempt to convert the head to an anterior position or to do version in the presence of a partially dilated cervix is inviting trouble.

I also believe that there should be no interference, even though progress is slow, until after two hours of second stage pain or one hour with the head on the perineum. In some cases, the head will come only to the midpelvis. In this series, 85.7 per cent of the primiparas and *72.2 per cent of the multiparas were* permitted a second stage of two hours or more. Fetal *heart tones are watched carefully. In some mothers,* dehydration will occur and dextrose may be given intravenously for food and fluid.

TABLE 3.—*Station of the Head in Early Labor*

| Station | Primigravida | Para II | Para III | Para IV |
|---|---|---|---|---|
| —4 | 2 | 0 | 0 | 0 |
| —3 | 7 | 1 | 0 | 0 |
| —2 | 7 | 1 | 2 | 2 |
| —1 | 14 | 7 | 2 | 2 |
| —0 | 22 | 5 | 1 | 1 |
| +1 | 10 | 7 | 1 | 1 |
| +3 | 6 | 1 | 1 | 0 |
| +3 | 2 | 1 | 0 | 0 |
| +4 | 0 | 0 | 0 | 0 |

If progress has stopped after two hours of complete dilatation with the head in the midpelvis or on the perineum, I believe that in the majority of cases the ideal treatment is manual rotation followed by forceps. Kushner and Wahrsinger[14] stated, "Manual rotation of the head followed by forceps application for extraction very frequently is a failure because of the difficulty in keeping the head in the anterior position while applying the blades." My experience has been so different from this, that, after twenty years, I still believe that there is no instrument which can rotate the head in any position of the pelvis with so little chance of damaging mother and baby as the human hand.

If the condition of the baby demands interference early in the second stage and the head is high at —1 station, version is safer than forceps with the head not engaged, but just a little more time may make considerable difference in station. If one does a version, one must always be sure there is no obstruction and no contraction ring.

If pains are not strong, one can occasionally permit a patient to go several hours in the second stage, but there is always the possibility of development of a contraction ring. In 1 case I delivered the patient twelve hours after delivery had been attempted in another town, the patient entering the hospital here exhausted and with complete dilatation but poor pain. She was given rest and fluids for six hours after admission, before delivery was effected by manual rotation and low forceps.

Table 4.—*Management of Persistent Occiput Posterior Position in This Series*

| Year | Manual Rotation Followed by Forceps | Bill's Modified Scanzoni | DeLee Key-in-Lock | As a Posterior (Occipitosacral) Position |
|---|---|---|---|---|
| 1942 | 12 | 0 | 0 | 0 |
| 1943 | 19 | 1 | 1 | 0 |
| 1944 | 9 | 0 | 0 | 1 |
| 1945 | 20 | 0 | 1 | 0 |
| 1946 | 19 | 1 | 0 | 0 |
| 1947 | 21 | 0 | 0 | 1 |
| Total | 100 | 2 | 2 | 2 |

*Technic of Manual Rotation.*—The patient is placed on the delivery table with buttocks well over the end of the table. Ether anesthesia was used in each case. After preparation and draping, the bladder is catheterized. Following this, a rather deep left mediolateral episiotomy is done and the whole hand is placed in the vagina and the position of the baby checked. Because of excessive molding of the head, it is often impossible to be sure of fontanels and sutures, so that one may search for an ear. The back of the ear will point to the occiput. The latter also can be verified by passing the hand upward along the occiput as this has an entirely different shape than the forehead. If a right occipitoposterior position is present I prefer to use the left hand internally, and if a left occipitoposterior position is present the right hand is used.

After certain identification of the occiput is made, the hand grasps the baby's head with the occiput in the hollow of the hand, and rotation of the head is effected by simple pronation of the hand, the occiput thus turning approximately 135 degrees to come under the symphysis. At the same time, the head is flexed.

If a left occipitoposterior position is changed by rotation to a left occipitoanterior position by means of the right hand, the latter holds the head from slipping back posteriorly and the left blade of the forceps is applied with the right hand in place. The hand is then removed and the right blade applied. If the occiput has remained anterior, then the baby is delivered by forceps exactly as in a primary anterior position. I prefer the DeLee modified Simpson forceps.

If the position is a right occipitoposterior, the left hand is used to do the rotation; I prefer to place the right blade of the forceps first, because its presence tends to prevent rotation back to the posterior position.

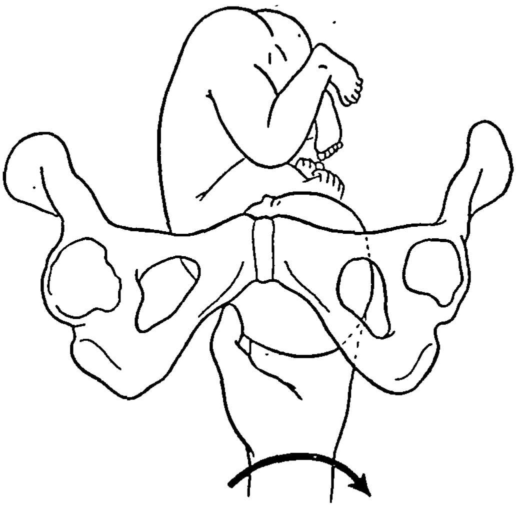

Fig. 1.—Drawing depicting manual rotation from the right occipitoposterior position.

In case the occiput does rotate posteriorly before the blades can be applied or locked, then external pressure on the forehead by an assistant with the hand above the symphysis will usually suffice to maintain rotation. If, however, this is not successful, the internal hand can, in addition to rotation of the head, also rotate the back by pressure on the posterior shoulder. Abdominal pressure may be used on the anterior shoulder to help rotation. Shoulder pressure was not necessary in any of these reported cases. If the shoulder and back are rotated, there is not the tendency of the occiput to rotate back to the posterior quadrant. If the head is displaced upward to a considerable degree, which is sometimes necessary, there is always danger of a prolapsed cord. This happened twice in this series, but no harm was done.

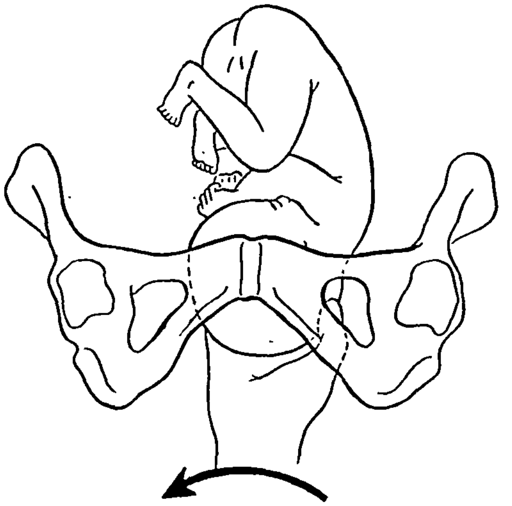

Fig. 2.—Drawing depicting manual rotation from the left occipitoposterior position.

Figure 1 illustrates rotation of a right occipitoposterior position and figure 2 rotation of a left occipitoposterior position.

*Rotation by Forceps.*—Rotation can be accomplished by the Scanzoni or Tarnier method, which has been improved by Bill[15] of Cleveland. The latter's results are excellent, but he reports version on over half of his cases of persistent occiput posterior position.

DeLee[16] has also described a type of forceps rotation which he termed the key-in-lock maneuver. This consists in application of the blades with the front to the sinciput and gradual rotation of the head, a few degrees at a time, by pushing the head slightly upward, slight twist and then traction with repeated reapplication of the blades until the occiput is gradually brought to the anterior quadrant, from where it is extracted as in anterior position.

If the occiput can be rotated only to the transverse, then a parietal-malar application is necessary unless the Kielland or Barton forceps are used. Langman and Taylor[17] stated preference for the Barton forceps, particularly with high transverse arrest.

Some obstetricians prefer to deliver some cases of occiput posterior position as occipitosacral, especially when the head is tightly wedged in the pelvis and the pelvis is of the anthropoid type. This was necessary twice in my series after failure of manual rotation. One was in a traumatic pelvis that was very questionable, but within five and a half hours of first stage pain and two hours of second stage the caput was visible, but station was only about plus 1 as there was tremendous molding of the head. Midforceps operation resulted in a 9 pound 3 ounce (4,167 Gm.) baby and a 3 degree laceration.

Because of long labor, with an exhausted patient and uterus, the dangers of postpartum hemorrhage must be kept in mind. Three of my patients required transfusion.

## MORTALITY AND MORBIDITY IN PERSISTENT POSTERIOR

In this group of 106 cases, there was no maternal or fetal mortality. Six patients showed morbidity according to the standard of American College of Surgeons. Causes were as follows: endometritis (1 case), cause unknown (1 case), pyelitis (2 cases), cystitis (1 case) and acute suppurative pyelonephritis (1 case). In the last case there was long labor; the patient passed blood from the bladder during the last of her labor and was hospitalized about six weeks.

## THE UNENGAGED HEAD

In addition to cases of persistent occiput posterior position, there is the group in which there is persistent nonengagement. These cases require careful study and evaluation of the pelvis. Several hours of labor may, however, decide the issue clearly. As previously mentioned, accuracy of station is of great importance. One can usually determine after a few hours of labor which cases will require cesarean section, because of the contracted pelvis with disproportion. With continued overriding of the head in a borderline pelvis and a failure of the Muller Hillis maneuver to bring the head to the spines, suspicion is warranted.

During the six year period covered in this analysis, there were seventeen cesarean sections, all low cervical, done when the occiput was in posterior position. Three of these were of the elective type, one done because of borderline pelvis, the patient being a 43 year old primipara who formerly presented a sterility problem, another with severe toxemia and the third with definite disproportion plus a rheumatic heart. Fourteen were done after trials of labor, varying from fourteen to forty-eight hours, and, in my judgment, all needed cesarean section and would also have needed cesarean section if the position had been anterior. There was no maternal mortality, and 1 baby in this group was stillborn.

## SUMMARY AND CONCLUSIONS

In the greatest number of cases of occiput posterior position, rotation will spontaneously occur and the patient be delivered with comparative ease. In cases of persistence of the unengaged head after several hours of labor, definite inlet obstruction is usually found. In my hands, manual rotation and forceps continues to be the most satisfactory means of dealing with the persistent occiput posterior position. One hundred out of 106 patients were so treated. The technic used is given. A reasonable duration of second stage is urged; so that the number of cases of persistent posterior position will be held to a minimum.

## ABSTRACT OF DISCUSSION

DR. E. L. CORNELL, Chicago: Occiput posterior positions are much more frequent than formerly supposed. One sees the patient today earlier in her labor, because of better prenatal instruction. In many, the rotation to the transverse and anterior positions take place relatively early in the first stage. Thus many posterior positions are missed if the patient is first seen after labor is well established. I am pleased to note that Dr. Gustafson does not induce labor in dystocia dystrophia. In my opinion it is nearly always fatal to do so. The patients will be much better off if allowed to go into labor spontaneously, when they will either deliver promptly or require radical treatment. As Dr. Gustafson has indicated, the diagnosis of the location and position of the head is of extreme importance. It is only thus that disaster is avoided. Terrible lacerations of the vagina and damage to the fetal head follow if this rule

17. Langman, L., and Taylor, H. C., Jr.: The Selection of Forceps for Mid Pelvic Arrest of the Vertex, J. Obst. & Gynec. **52**: 773, 1946.

is not observed. Since the advent of analgesia, the suffering formerly seen in the first stage of labor can be avoided. Now time can be safely taken for the first stage of labor. I still do not use morphine as the sedative, except in the occasional case, because of its effect on the respiratory apparatus of the fetus. I would advise the use of barbiturates or meperidine hydrochloride in adequate dosage. Dr. Gustafson did not mention intact membranes, after dilatation is complete, as a cause for the delay in the rotation of the head anteriorly. I have made it a practice to rupture the membranes artificially when dilatation is complete; thus the full force of the uterine contraction is utilized to cause the head to descend and to rotate. It often shortens the labor and converts the delivery to a simple procedure. The membranes should not be ruptured if version and extraction are under consideration, because the liquor aminii may be all drained away. Manual rotation of the head should be accomplished without disengaging it. I have found it possible in the large proportion of cases to rotate the head by placing two fingers in the upper lamboid suture and exerting pressure upward in the wide arc of the circle. Rotation by forceps, no matter what make, is fraught with the danger of lacerating the vagina badly. It is not the operation of choice for the occasional obstetrician. I make a plea for the patient and the consulting obstetrician: Please do not interfere with progress of labor; support the patient with liquids and easily digestible food. Call the consultant early before the case becomes hopeless with respect to the baby.

Dr. Gerald Rogers, Oklahoma City: The more patients I see, the more I am led to the conclusion that the primary occurrence of occiput posterior position, as well as its abnormal persistence, necessarily implies the existence of some degree of bony pelvic asymmetry, deformity or cephalopelvic disproportion. Occiput posterior position is not necessarily and per se a definite pathologic entity; it becomes pathologic by reason of its persistence, and the cause is practically always an anomaly of pelvic architecture. Therefore, the problem of management should be predicated on the existence and nature of bony dystocia rather than primarily on the troublesome position caused thereby. The most important phase in management consists in competent antenatal estimation of the pelvic capacity or adequacy, taking account not only of the inlet but particularly of the midplane and the outlet. Roentgenographic mensuration should be increasingly utilized in estimating the borderline and definite contractions. There is no substitute for manual pelvimetry and no argument but that the fetal head is the most practical pelvimeter in the final analysis. I agree that manual rotation of the occiput is the simplest and safest method, with due precaution to prevent its dislocation from the pelvis and possible prolapse of the cord. Surgical anesthesia—I prefer cyclopropane with oxygen—adequate exposure and free mobilization of the head, usually with medicinal soft soap, facilitate all attempts at rotation. My geographic training prescribes the DeLee-Simpson forceps wherever forceps are indicated. I use the key-in-lock maneuver. I wish to congratulate the essayist on his conservatism and his morbidity, rate; especially I agree that there can be no fixed rules governing the length of time to wait in the second stage. If the position of the head is abnormal, if progress is arrested, this may be corrected earlier than the traditional two hours, and much may be gained by correcting the position and delivering the patient. I would not have any feeling of satisfaction if the head had finally rotated spontaneously after four or five hours of hard second stage labor, knowing that I could have corrected this in a few minutes several hours previously.

Dr. Buford G. Hamilton, Richmond, Mo.: It is evident that the obstetricians' problems are in keeping with the population of their special section of the country. I have observed that reports of obstetric problems in the thickly populated areas with a large foreign group are different from the Kansas City area. Western Missouri and Eastern Kansas are agricultural areas, with little or no segregated areas, with wide open spaces, with a typical American population and a small foreign population and with possibilities of a generous balanced diet for all. Thus a pelvic problem is seldom encountered there. The problem relates to the cervix and, in a few cases, the lower uterine segment. The type of pain with both large and small babies concerns each of us. Roentgen pelvimetry is followed in all doubtful cases and in all cases of delayed labor. Roentgen pelvimetry will be disappointing until such a time as the various national obstetric and gynecologic societies jointly establish a standard of roentgen pelvimetry, that can be followed in all obstetric departments and in private hospitals. To date my co-workers and I have analyzed about 1,500 cases of occiput posterior position, personally cared for in labor. Our analysis of the groups reported show an instance of 47 per cent occiput posterior position. Our various percentages are in keeping with Dr. Gustafson's report. Then, since we have accepted the preliminary stage of labor as a part of labor, we find there is little difference in the duration of labor in anterior and posterior positions. It is for this reason that we have in each report said that the only difference between the two positions is in time and the ability to wait. With food, fluids and rest judiciously used, keeping a patient with a moist tongue and a pulse rate below 90, time and management seem to be the answer to our problems. I do not know why rotation takes place in any patient or where to expect it to take place, if at all. Often in seemingly hopeless cases, with more fluids and rest I have seen spontaneous deliveries or changes in station that made delivery safe. Williams, DeLee, Litzenberg, Schwarz and other old masters have said, "Wait!" Realizing that cervical repair has been disappointing in my hands and that uterine inertia and cervical dystocia have been lessened in keeping with my management of labor, I am convinced of the importance of food, fluids and rest.

---

# SURGICAL TREATMENT FOR COARCTATION OF THE AORTA

## Experiences from 60 Cases

ROBERT E. GROSS, M.D.
Boston

Coarctation is a congenital obstruction of the aorta; a segment of the vessel has only a tiny lumen or, indeed, may be entirely obliterated. It is four or five times commoner in males than in females. There have been many excellent descriptions of the pathologic structure, particularly in reference to the development of collateral arterial channels.[1] The condition can be quickly recognized during life by adequate physical examination. The seriousness of the prognosis has not been appreciated by most physicians.

In an attempt to determine the prognosis for patients with coarctation of the aorta, Reifenstein, Levine and Gross [2] reviewed postmortem material from the larger hospitals of the Boston area and picked out for study all cases of coarctation whether or not the coarctation had contributed to death. In this way statistics were compiled which would in a rough way reflect what has been happening to persons with coarctation in the population at large. In general, the subjects could be classified into four groups of approximately equal size:

1. About one quarter (26 per cent) of the patients lived a long life, had little or no incapacitation and were able to exist with a reasonably high degree of efficiency. Some lived to advanced old age. Some had mild or moderate disability, which, however, was sufficient to take them to a physician or hospital where appropriate studies indicated the existence of an aortic

Read before the Section on Surgery, General and Abdominal, at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 24, 1948.

[1] Bramwell, C., and Jones, A. M.: Coarctation of the Aorta: The Collateral Circulation, Brit. Heart. J. 3:205-227, 1941.

[2] Reifenstein, G. A.; Levine, S. A., and Gross, R. E.: Coarctation of the Aorta: A Review of 104 Autopsied Cases of the "Adult Type," Am. Heart J. 33:146-168, 1947.

block. In some instances, the abnormality was completely unsuspected until the time of autopsy.

2. About one quarter (22 per cent) of the subjects died *from bacterial endocarditis or aortitis, the infecting* organism usually being the Streptococcus viridans. Obviously, the threat of such infection is greatly minimized today when various chemotherapeutic agents are available. However, it is well to point out that sterilization of the blood stream may be followed by irremediable myocardial damage or weakness and dilatation of an aortic wall which have resulted from a burned out infection.

3. In about one quarter (23 per cent) of the cases there was sudden death from rupture of the aorta. Aortic rupture was most apt to be preceded by hypertension, but it could occur in the presence of relatively normal pressures.

4. About one quarter (28 per cent) of the patients died because of the hypertensive state. Deaths from cardiac failure were about twice as common as fatalities from intracranial hemorrhage.

The majority of the deaths from rupture of the aorta or from intracranial hemorrhage occurred in the second and third decades. Deaths from bacterial endocarditis or aortitis occurred throughout the first five decades, but were most common in the third decade. Deaths from congestive failure were most common in the third, fourth and fifth decades. The average age at death (including those who died of incidental causes) was 35 years. If patients were excluded who died from "incidental" causes, the remaining patients (those who died from coarctation or its complications) had an average age at death which was reduced to about 30 years.

The aforementioned study indicates that, while some persons *may live a long and useful life with coarctation* of the aorta, the abnormality is one which brings tremendous hazards to its possessor. Certainly, attempts to remove aortic obstructions are worth while, provided that such operations can be carried out without prohibitive mortality rates.

### PHYSICAL OBSERVATIONS

Fortunately, coarctation of the aorta produces changes in the peripheral parts of the vascular system which make it easy to recognize the underlying abnormality. By physical examination, the diagnosis can be established quickly and with great accuracy from a few simple readily discernible variations from the normal.

Of greatest importance is the reduction of arterial beats in the lower part of the body. Palpation of the femoral arteries *will reveal a greatly diminished or* an absent pulsation. In some cases a weak femoral pulsation can be felt, but the impulses come much later than the radial artery pulsation—a reversal of normal—indicating that blood is reaching the femoral region by way of *long tortuous channels* through the collateral beds. If femoral pulsations appear to be diminished in intensity, the pressures in the popliteal arteries should be checked with a sphygmomanometer. Normally, the pressure in the legs should be 30 or 40 mm. of mercury higher than that in the arms, but in the presence of an aortic block the leg pressures are decidedly below those of the arms.

Whenever an aorta is obstructed there is a well pronounced tendency for the pressures in the arms to be raised to the upper ranges of normal or to hypertensive levels. In the majority of patients, and certainly in those beyond the first decade, there is hypertension, ranging anywhere from mild to pronounced degree. When any patient is found to have elevated pressure in the arms, the examiner *should check the circulation in* the legs, to seek for coarctation as a possible cause for the hypertension.

Differences of pressure in the two arms greater than 30 or 40 mm. of mercury suggest that the aorta is blocked somewhere proximal to the origin of the left subclavian artery. That this is not necessarily true is indicated by 2 of our patients who had decided discrepancies in the arm pressures; in both subjects the coarctation was well below the origin of the left subclavian artery, but the first part of the subclavian artery was abnormally small or atretic in each case.

A blood pressure determination which is made on an office visit or during rest in bed must not be taken as an indication of the pressure which exists when the patient is performing exercise or is under physical *strain. A normal person will respond to moderate* activity by elevation of the blood pressure 20 to 40 mm. of mercury, but a patient with coarctation of the aorta (in whom a large quantity of blood cannot pass out into the peripheral vascular bed) will respond to exercise by extraordinary rises in the arm pressures, frequently amounting to 100 or 150 mm. of mercury above the resting level.

Evidence of collateral arterial circulation is often observed, but is by no means constant in appearance. It is less apt to appear in children; it is commonly found in adults. It is more easily detected in thin subjects. Pulsations may be seen and felt medial to and below either scapula, above and beneath the clavicles and along either side of the sternum. From the internal mammary arteries pulsations may extend *downward onto the abdomen, along the course of the* epigastric arteries. Pulsations which appear on the anterior part of the chest are apt to be somewhat more intense on the right than on the left.

Murmurs are rather variable. Frequently, but not *constantly, there is a systolic murmur of mild or moderate* intensity over the precordium, which is transmitted with almost equal intensity to the left side of the interscapular area. The level of the point of maximum intensity of murmur to the left of the spine is no indication of the actual level of the aortic block. The systolic murmur which has been so frequently described in connection with coarctation may arise from the constricted segment itself, but in some instances it comes from an angulation of a channel, such as occurs in the region where the internal mammary artery takes off from the subclavian artery. Furthermore, a systolic murmur may originate from an associated interventricular septal defect or, occasionally, from a bicuspid aortic valve. In some patients there is no murmur. In occasional instances, there is a continuous murmur which *is accentuated during systole and which dies off in* diastole. This may have a central origin from an associated patent ductus arteriosus, or it may have a peripheral origin from blood rushing through tortuous and greatly dilated collateral vessels. The murmurs in patients with coarctation of the aorta are inconstant in appearance and are variable in intensity and in timing; little reliance can be attached to them in determining the presence or absence of a coarctation.

In middled-aged subjects electrocardiographic tracings or a poor tolerance for exercise may give evidence *of myocardial damage and cardiac insufficiency.* The eye grounds may show nicking of vessels, narrowing of some channels or hemorrhages of the retina, which can occur with any hypertensive state.

### ROENTGENOLOGIC DATA

The common location for coarctation is just beyond the distal end of the aortic arch. This usually produces certain roentgenologic signs. In infancy or in childhood, examination of the chest may show only cardiac hypertrophy or other changes which do not clearly indicate the type of cardiovascular abnormality which is present. Beyond the first decade of life, roentgenologists are usually able to make a positive diagnosis of aortic coarctation from a few simple observations. The heart is apt to be enlarged. Cardiac hypertrophy and dilatation may be pronounced when there has been long-standing hypertension. The aortic knob is usually small and lacks its normal prominence. In some instances, it is possible to see a slight indentation of the first part of the descending aorta, especially if the patient is turned in just the right angle to throw the aortic shadow off the spine shadow. Most important is the observation of notching or scalloping along the inferior edges of the posterolateral portion of the ribs, where tortuous and pulsating intercostal arteries have eroded the adjacent bone. Rib notching is seldom found in the upper and lower two or three ribs.

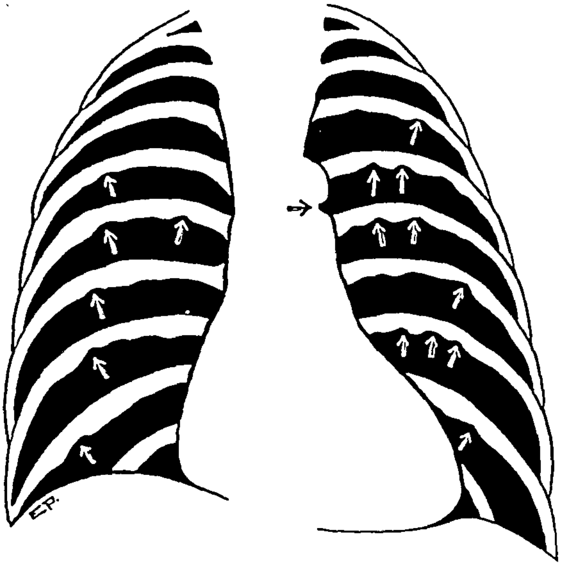

Fig. 1.—Tracing taken from a roentgenogram of a man with coarctation of the aorta. The heart is enlarged. The aortic knob is small. The black arrow points to an indentation in the descending aorta. The white arrows indicate some of the notches on the inferior edges of various ribs.

In rare instances a coarctation may be in the lower portion of the thoracic aorta or even in the upper part of the abdominal aorta. In such circumstances the aortic knob should be normal in size and prominence, and if notching appears on the ribs it should involve only the lowermost ribs.

For exact confirmation of diagnosis and for visualization of the anatomic abnormality, angiocardiography is most useful. I have had some disappointments with the intravenous injection of iodopyracet ("diodrast") because the material has become too diluted by the time it reaches the aorta. Direct injection on the arterial side of the circulation may give better visualization of the aorta. I prefer to do this by retrograde introduction of a polyethylene catheter through the left axillary artery, threading the catheter back through the subclavian artery into the aorta. Iodopyracet injected through this catheter will reach the aorta in very high concentration, and excellent visualization can be obtained.

### SURGICAL TECHNICS

Surgical attack on coarctation of the aorta has been preceded by extensive laboratory investigations [3] which were designed to study the feasibility of resection of segments of the thoracic aorta and to test methods for anastomosis of the remaining ends of the vessel. In dogs it was found that short portions of aorta could be removed safely and that the vessels could be reconstructed with a high percentage of animal survivals, without dehiscence of the suture lines and without thrombosis at the anastomoses. In experiments with different types of arterial suture, it was proved that the most reliable method of anastomosis was that in which the vessels ends were brought together with a continuous mattress suture of silk, with the stitches taken through the entire thickness of the aortic wall and the ends of the vessel turned outward. This brought intima to intima, and, if properly performed, no silk was exposed on the internal surface.

The technical details of operation have been fully described elsewhere [4] and need not be repeated here; however, it is well to emphasize a few points. Intratracheal anesthesia is essential. I now believe that cyclopropane anesthesia for the entire duration of these long operations is dangerous, but it does have distinct advantages for short periods when the surgeon is particularly desirous of having the respiratory movements at a minimum. Ether anesthesia with a closed system for the greater part of the operation has been found to be satisfactory.

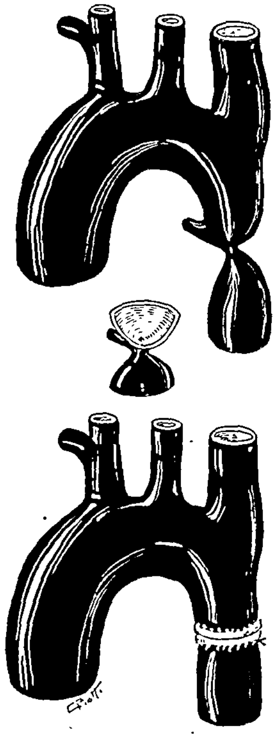

Fig. 2.—Surgical treatment of coarctation of the aorta. *Above*, a common site of coarctation, at or near the attachment of the ligamentum arteriosum. *Middle*, segment of narrowed aorta which has been excised. *Below*, reconstruction of aorta by end to end anastomosis.

It is important to have a cannula in a vein (preferably an ankle) for administration of blood throughout the procedure. Blood loss may be pronounced during the opening of the chest, because of the great vascularity of the thoracic wall. Furthermore, injury to one of the large collateral channels adjacent to the aorta may give rise to serious hemorrhage. Dry sponges and packs are used, so that they can be weighed to determine how much blood they contain. This figure, along with the amount of blood in the suction apparatus bottle, furnishes a rough estimate of the total blood loss and can guide the replacement therapy. It is highly important to give adequate amounts of blood, so that shock and cerebral anoxia are avoided. Infusion of 1,000 or 2,000 cc. of blood is common practice; in a few cases larger amounts have been necessary. The intravenous injection of dextrose during so long an operation is likewise of great value in keeping the patient in a stable condition. Injection of dextrose through the blood transfusion set is apt to lead to clogging of the apparatus; hence, it has been my practice to give the dextrose solution through an entirely separate apparatus for intravenous administration.

The surgical approach is through a long incision medial to and below the left scapula, running well around below the left breast. Previously, most of the fourth rib was removed from its bed, but I have found that this will give a depression deformity of the chest in some cases. More recently the chest has been entered throughout the entire length of the fourth interspace. Short segments have been removed posteriorly from the third, fourth, fifth, sixth and seventh ribs, but it is usually necessary to cut only the fourth and fifth intercostal muscle bundles. A wide exposure is essential. This transpleural approach to the aortic arch and first part of the descending aorta permits an adequate view of the region and will allow mobilization of the aorta from its bed.

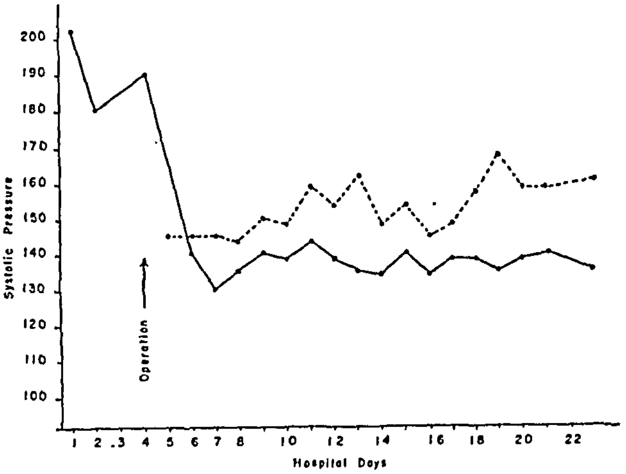

Fig. 3.—Blood pressure chart from a 23 year old woman, who was treated for coarctation of the aorta. The solid line indicates systolic pressure in the arms. The dotted line indicates systolic pressures in the legs. (Prior to operation blood pressure readings could not be obtained in the legs with a sphygmomanometer).

If possible, the intercostal arteries are saved by applying small serrefine clamps to them temporarily. In some cases it is necessary to doubly ligate and divide the upper one or two intercostal arteries, if they lie in a position which will interfere with subsequent sewing of the aortic wall. As a general principle it is well to preserve as much of the collateral blood supply as possible, but in no circumstances should the collaterals be kept if in doing so there is any compromising of the establishment of a first class aortic anastomosis. Appropriate noncrushing clamps are applied above and below the constricted area of aorta, and the narrowed portion is cut away. The remaining ends of the aorta must be fashioned to have lumens of nearly equal size. By handling the clamps, the assistant can bring the ends of the aorta together and maintain them in juxtaposition while the surgeon sews the vessels together; there is no tension whatever on the sutures while they are being placed.

A high coarctation, which appears at, or very close to, the origin of the left subclavian artery can be treated by placing the uppermost clamp directly across the aortic arch and the left subclavian artery, temporarily closing off the latter. This permits the lower end of the aorta to be brought up directly to the aortic arch itself. In 12 cases of the present series a high anastomosis of this sort was required.

In the segments of aorta which were removed, the lumen was usually a tiny opening, no more than 1 or 2 mm. in diameter, and in no specimen was it more than 3 mm. in diameter. In 6 cases of this series there was an associated patent ductus arteriosus, the ductus in 5 instances communicating with the aorta above the aortic obstruction, and in 1 instance it led into the lower aortic segment. In each case the ductus was completely divided and the pulmonary end was closed by continuous silk suture. The distal end of the ductus was, of course, cut away and removed with the narrowed segment of aorta.

In several instances operation was limited to exploration of the chest, because the observation indicated a long constriction in the aorta. In a few cases, when a relatively long aortic segment was removed, there was great difficulty in getting the ends of aorta together because of great tension in the aorta. Finally, in several other operations an insufficient amount of narrowed aorta was cut out, because of the fear that removal of more vessel would lead to insurmountable difficulties in getting the remaining ends of aorta together; this meant that an anastomosis was made in such a way that much of the obstruction was removed, but that a lumen of ideal size was not created. These three sets of circumstances have long made it evident that surgical treatment for coarctation would receive great impetus if it were always possible to remove an entire constricted area (and not merely the most constricted area) and to bridge the gap thus made by a graft or transplant. If it were feasible to transfer safely a large vessel and implant it in this way to fill a gap, the surgeon would be able to cut above and below and reach back to normal-sized aorta and routinely establish an aortic pathway of normal size. Obviously, there is no other vessel in the body which is large enough to supply a segment for filling in an aortic gap. If grafting is to be done, the graft must come from some other person (who has died in an accident or has died after some nonseptic disease). Experimental work[5] from the laboratory (on dogs) seems to indicate that if arteries can be obtained within four or five hours after death they can be transferred to a recipient animal with an excellent chance of survival. Furthermore, methods have been devised whereby grafts can be preserved for periods as long as thirty-five to forty days before being implanted into recipient animals. Tissue culture studies[6] show that vessels preserved in the manner employed are viable for as long as thirty-five or forty days.

In 1 child of 7 years, removal of an aortic coarctation left aortic ends which were widely separated. An aortic graft from another person (which had been

preserved thirty days) was sutured into place to fill the gap. This graft was 5 cm. in length. Postoperative studies indicate that an excellent aortic pathway had been established. This boy appeared to be in excellent health at the time of hospital discharge and at this writing (only one month since operation).

## RESULTS OF OPERATION

Sixty patients with coarctation of the aorta have been operated on. They varied in age from 5 to 30 years. The over-all results are summarized in table 1. In 6 cases, the mediastinum was explored but the obstruction could not be removed because of the conditions which were found, such as regional inflammatory changes from an old burned out infection and a very long segment of narrowed aorta. In 2 other patients excision of the coarctation with end to end reconstruction of the aorta seemed impossible; it was therefore decided to sever the left subclavian artery high in the thorax, after the method suggested by Blalock and Park,[7] turning down the proximal end of the subclavian for end to end anastmosis with the distal segment of aorta. In the first case there was fair, but incomplete, alleviation of hypertension. In the second case (treatment was too recent for final evaluation) the minimal blood pressure changes in the early postoperative period were discouraging as far as the ultimate relief of hypertension is concerned. In the remaining 52 patients the narrowed segment of aorta was excised and an end to end anastomosis was performed. In a few of these the size of the anastomotic opening was smaller than might be desirable, whereas in the vast majority of them it was possible to establish a lumen which had essentially the diameter of the aortic arch. In these 52 cases there were 7 deaths, the causes for which are listed in table 2. In 1 patient there was no relief of hypertension, and in 3 others there was a moderate lowering of the arm pressures; in all of these 4 instances technical difficulties at operation made it impossible to establish an aortic pathway of satisfactory size. In the remaining 41 cases there was complete cure of hypertension; the pressures in the arms fell to normal levels, and there was a concomitant rise in leg pressures to figures equal to, or above, those in the arms.

A high degree of hypertension prior to operation does not necessarily indicate that serious difficulties will be encountered at the operating table, nor does it vitiate the possibility of obtaining a satisfactory postoperative result. Indeed, some of the best effects have been seen in patients who have had systolic arm pressures well above 200 mm. of mercury; they had falls of as much as 100 mm. of mercury in the postoperative period. However, it is certainly true that long-standing hypertension, particularly in male subjects and especially in those beyond the second decade of life, may be expected to increase the surgeon's problem, because the continued pounding of the aorta sets up fibrosis in the tissues of the aortic bed which make it difficult to free the vessel from surrounding structures. Furthermore, long-standing hypertension, especially in male subjects, will lead to greater loss of aortic wall elasticity, so that (following coarctation resection) it will be troublesome to get the remaining ends of the vessel together for establishment of a satisfactory anastomosis.

The age of the patient has an important relation to the postoperative result which can be expected. Obviously, in older subjects, when there are more advanced sclerotic changes in the arterial wall, the risk of operation will be greater and the chances of obtaining a satisfactory aortic union will be less. Operations on older subjects necessarily imply that one is frequently accepting patients who have such conditions as advanced cardiac enlargement, myocardial damage and loss of cardiac reserve. It is difficult to define precisely the upper age limit of operability. In the early part of this work an opinion was expressed that operation should be reserved largely for patients in the childhood and teen age periods, but now surgical experience has extended so that it is possible to tackle cases in the older age groups without assuming too high a risk. Some excellent results have been obtained in patients in the late twenties. However, there can be no doubt that the greatest satisfaction will always be obtained in younger subjects and that the chances for beneficial effects will diminish as one deals with older and older patients.

Table 1.—*Data in Sixty Operations for Coarctation*

| Operation, Result | No. of Cases |
|---|---|
| *Exploration only* | 6 |
| Subclavian anastomosis | 2 |
| Resection of coarctation; end to end anastomosis | |
| Death from various causes | 7 |
| No relief of hypertension | 1 |
| Fair relief of hypertension | 3 |
| Complete relief of hypertension | 41 |

Table 2.—*Causes of Death Following Excision of Coarctation*

| Patient | Age, Yr. | Cause of Death |
|---|---|---|
| P. S. | 7 | Too sudden removal of clamp |
| A. S. | 30 | Hemorrhage from anastomosis (?) (sudden death in 24 hr.) |
| M. B. | 15 | Cerebral anoxia (death 3 days later) |
| E. T. | 9 | Associated rheumatic mitral stenosis (death 1 week later) |
| J. W. | 14 | Death due to cyclopropane (?) (sudden death at end of operation) |
| W. C. | 16 | Cerebral anoxia (death 4 days later) |
| J. H. | 21 | Aortic valve insufficiency (sudden death 14 hr. postoperatively) |

In general, there are several reasons why small children should not be operated on: 1. The risks in babies or very young children would probably be extraordinarily high because the collateral channels are not yet well developed. 2. The aorta is not yet large enough to work on with facility. (It was my experience in experimental procedures that dogs under 35 or 40 pounds [16 or 18 Kg.] in weight had aortas too small to suture with ease.) 3. An aortic lumen may be established at the anastomosis which is satisfactory for a child a few years of age, but it will probably be insufficient in size when the person grows to maturity. Of course, it is possible that an arterial anastomosis will enlarge slightly as the subject becomes larger, but it is almost inconceivable that it will keep pace with the augmentation in size of the person as he grows to adult proportions. There is usually no urgency about operation in very young subjects. I have observed 6 babies within the first year of life who had pronounced cardiac enlargement and evidence of decompensation because of an aortic obstruction, but it was possible in all instances (with hospitalization, oxygen therapy, digitalization and the like) to tide them over for a few months and to have them regain compensation—presumably as they increased the size of their collateral channels. It is probably wise to avoid operation before 6 or 8 years of age unless there are some specific reasons for earlier intervention.

---

[7] Blalock, A., and Park, E. A.: Surgical Treatment of Experimental Coarctation (Atresia) of Aorta, Ann. Surg. **119:** 445-456, 1944.

It is important to analyze the operative and postoperative deaths (table 2) in order to reduce the number of fatalities from this type of operation in the future. Of the 7 deaths only 1 was directly connected with the aortic abnormality and can be accepted as a reasonable risk of this type of operation. Probably all of the other deaths could have been avoided by (1) exclusion of patients in whom there is important mitral stenosis or aortic insufficiency, (2) avoidance of cyclopropane for the entire operation, (3) allowing for a slow readjustment of the circulation at the time of removal of the clamps and (4) administration of adequate amounts of fluid and blood during operation. I have no doubt that future series of surgically treated patients with coarctation will carry lower mortality rates than have been possible in the initial phases of this work.

In 1 subject, not included in the present series of 60 cases, excision of the coarctation left a long gap which was impossible to close because of the inelasticity of the remaining aortic ends. A graft 5 cm. in length was inserted between the two ends of the aorta. Insufficient time has elapsed for final evaluation of this technic, but in the month after operation there was complete relief of hypertension in the arms and a raising of pressures in the legs to a level which was higher than that in the arms. The ease with which this graft could be sewed into place to establish a suitable aortic channel would seem to give great promise for the treatment of coarctation in patients of mid-adult life, for whom direct anastomosis of aortic ends may be difficult or impossible. If further trial of these aortic grafts from one person to another indicates that they are relatively safe to use, then I believe that surgical treatment for coarctation of the aorta can be greatly extended and can be offered to patients in older age groups.

Prior to the time when patients had been operated on for coarctation of the aorta there were some theoretical reasons why removal of an aortic block might not be particularly effective in relieving hypertension. Presumably, an aortic obstruction proximal to the renal vessels would lead to renal ischemia of a degree which would produce permanent renal damage—which would then continue the hypertension even though the aortic block were excised. It is now impossible to give credence to this theory, since sufficient experience has accumulated to indicate that if the aortic block is completely removed, the hypertension will disappear.[8] As a corollary of these remarks it should be added and emphasized that the surgeon's duty is not only to remove some of the narrowed area but to remove all of the coarctation, so that a lumen is established which approaches the size of a normal aorta.

Surgical correction for coarctation of the aorta is an undertaking of considerable magnitude. The procedure is time consuming and is certainly accompanied with dangerous pitfalls if one attempts to compromise on the steps which demand patience, gentleness and great accuracy of technic. These operations are apt to be exhausting for the surgeon, anesthetist and the entire team, but they have great compensation in the form of extremely gratifying results whenever hypertension is relieved.

### SUMMARY AND CONCLUSIONS

A firm foundation of laboratory experimentation indicates that sections of the thoracic aorta can be excised and that the remaining ends of the vessel can be brought together by appropriate end to end anastomosis. After testing various types of aortic reconstruction, there seems to be no question that the best repair can be obtained by a union in which mattress sutures of silk grasp the entire thickness of the arterial wall and turn the ends of the vessel outward.

Experiences are summarized from 60 patients who were operated on for correction of coarctation of the aorta. Fatality rates have not been excessive for a major operative procedure in its developmental stages. Without question, many of the deaths in this series could have been avoided by the procedures and precautions which are now being employed. Experience which has now been gathered over a period of three years of surgical treatment for coarctation of the aorta indicates that in the vast majority of subjects it is possible to remove the aortic block and to obtain relief or complete cure of the hypertension.

## ABSTRACT OF DISCUSSION

Dr. Willis J. Potts, Chicago: This superbly illustrated dissertation on surgical treatment for coarctation of the aorta, based on this remarkable series, makes no comment more appropriate than, "Well done." The apology for the mortality rate of 7 in 60 cases is entirely out of order. The mortality of about 10 per cent in an operation this formidable is truly enviable. In regard to the transplantation of preserved aorta, are the laws of physiology and living anatomy immutable, or can they be changed? The aorta is a very complex structure, tough because of its elastic membrane, yet very fragile. Will this highly specialized tissue yield in time to the connective tissue, and will it eventually yield to the onslaught of continued pressure in the formation of an aneurysm? It is brilliantly conceived, and time only will tell whether it will work. If Dr. Gross says that it will work, it will work. It will certainly solve many of our difficulties. I want to present yet another clamp hitherto unpublished. What has worried surgeons, especially in the treatment of patent ductus arteriosus, has been the problem of a slipping clamp. This clamp has been built on the basis of the Indian fakir who walks on many nails, and because he steps on many points he does not injure the sole of his tough foot. This clamp at the top is approximately 1 mm. wide. In it have been formed many tiny points, forty to 1 inch (2.5 cm.). The hub of the clamp is so constructed that the jaws can coapt but cannot interdigitate. In considerable work on animals I have found it is impossible to injure the aorta. These tiny points catch in the adventitia of the vessel and will hold even though considerable traction is made on them. This was based on the development of clamps for the division and suture of patent ductus arteriosus. One clamp is put on the aortic side—it is about 1 mm. wide—and the straight clamp is put on the pulmonary side. Then the ductus can be divided, leaving the entire length of the ductus between the clamps for division and suture. In a boy 16 years of age who had a blood pressure of 250 in the arms and about 100 in the legs and a greatly enlarged heart, I employed the principle of this clamp. He had no stump; his subclavian artery simply made an arch and continued upward.

---

[8] Crafoord, C., and Nylin, G.: Congenital Coarctation of the Aorta and Its Surgical Treatment, J. Thoracic Surg. **14:** 347-361, 1945.

There was a stricture which was less than 1 mm. in size. The long clamp was put across the top, and, according to Dr. Gross' technic, which personally I prefer, of turning the vessel over, I sutured the posterior row and then turned it back and sutured the anterior row. Whether there is any advantage with such a narrow clamp in having part of the blood continue through the subclavian during the operation I do not know. The boy's blood pressure dropped immediately after the operation to 150 and remained at that level, and the pressure in his legs came up to approximately 150.

Dr. Richard B. Capps, Chicago: The development of surgical methods for the correction of congenital cardiovascular defects is one of the most important scientific achievements of the last decade. Dr. Gross has been one of the most brilliant workers in his field. As an internist, I would like to emphasize two points that Dr. Gross made. In the first place, coarctation of the aorta has usually been looked on as one of the congenital cardiovascular defects with an excellent prognosis. Dr. Gross in a study made in the last few years has shown that this was a misconception. He found that only 25 per cent of these patients live a normal life. This fact obviously justifies one in undertaking a fairly considerable surgical risk in trying to correct the condition. The second point I should like to make is the importance of early recognition. Dr. Gross has shown that it is desirable to operate on these patients before they are too old. I feel certain that the condition in a large percentage of cases is never diagnosed at all, and certainly in a large percentage it is not recognized until too late, until the patients have reached an age wherein surgical mortality is considerably increased. This means that internists and general practitioners must bear this condition in mind, and when they have a patient with hypertension, a patient with murmurs or arterial pulsations in unusual places, they should always palpate the femoral pulse and, if necessary, determine the blood pressure in the legs. Only by a wider recognition of this condition in its early stages can the full value of the new technics be realized.

Dr. Alfred Blalock, Baltimore: Dr. Gross and Dr. Clarence E. Crafoord of Stockholm are certainly to be congratulated for their excellent work on coarctation. My co-workers and I have operated on 26 patients with coarctation of the aorta, in most of whom we have used an end to end anastomosis between the proximal and distal segments. In several patients, we have used the subclavian as a by-passing artery, but certainly the end to end anastomosis is to be preferred. There are still instances in which one will have to use the subclavian artery unless the interesting use of aortic grafts as described by Dr. Gross proves to be safe and practical. These are the instances in which the constricted area in the aorta is unusually long and those in which the aorta is decidedly diseased.

Fifteen of the 26 patients on whom we have operated were more than 20 years of age. We have lost only 1 patient in this older age group, whereas 2 of the 3 deaths have been in the younger age group. These 2 younger patients had other congenital anomalies. I know that for a while Dr. Gross was not operating on patients over the age of 16, and I would like to ask him whether his views in that regard have been altered. Several days ago, I operated on a man of 41 years of age who had severe hypertension, severe headaches and severe precordial pain and who insisted on having the operation performed. It was found that his aorta was in suitably good condition for an excision of the stenotic area and an end to end anastomosis. I think that he is the oldest patient thus far to have been operated on for this condition. I thoroughly agree with what Dr. Gross has said—and Dr. Crafoord has emphasized this repeatedly—that one should save the collateral intercostal arteries. Not only are they helpful in conducting blood to the lower part of the body, but preserving them actually makes the operative procedure easier. The ligature is apt to cut through these thin-walled dilated intercostal arteries if they are ligated. Since these intercostal arteries run in an upward direction, I do not believe that their preservation interferes at all with the approximation of the proximal and distal segments of the aorta. As Dr. Gross has said, it is the division of the ligamentum arteriosum that really gives one the mobility and the length that one needs. In patients who have a very short proximal segment of the aorta, we use a modification of the Potts aortic clamp on this proximal segment. The back part of the clamp is narrower than the Potts aortic clamp, and one may place it on in the crotch between the left carotid and the left subclavian arteries. By this means, the proximal aorta may be completely occluded and the left subclavian artery partially occluded, thereby giving one a proximal stump of more adequate length. We have found the use of this clamp very helpful. I wish to congratulate Dr. Gross on this excellent presentation and particularly on the newer phase of the work that he has brought out, namely, the use of homogenous aortic grafts.

Dr. Egbert H. Fell, Chicago: I believe that it would be a mistake if some neophyte did not get up and express appreciation to Dr. Gross, Dr. Potts, Dr. Blalock and Dr. Shumacker for their excellent teachings and writings which have meant so much to us in preparing to give surgical relief to those with congenital cardiovascular diseases. There are three points I should like to make. One is that if one visits their clinics and watches them, one realizes the importance of teamwork—teamwork among pediatricians, cardiologists, anesthetists and nurses—and the importance of an excellent surgical team. At the Cook County Hospital and the Presbyterian Hospital of Chicago, we have successfully operated on 3 patients with coarctation, all children and all the operations done after the teachings and instructions of Dr. Gross. I wonder whether Dr. Craig, from his study of hypertension, has any idea how many children were found with hypertension that had no femoral pulse. Palpation of the femoral pulse is an important part of a routine physical examination. One of these children was a small boy, 10 years of age, with hypertension (140) and no pulsation in the legs. The larger boy had a pressure of around 200, with no pulsation in the legs. The larger of the two was 13 years of age and undergoing adolescent changes. These children grow rapidly during adolescence and have well developed shoulders. Both boys appeared normal, and yet both were greatly handicapped because of the hypertension. Drs. Gross and Blalock have made great contributions. If physicians are more careful in physical examinations they will be able to convert a seriously handicapped patient to a normal person.

Dr. Norman E. Freeman, San Francisco: Dr. Gross is indeed to be congratulated on the splendid results that he has obtained. He spoke of visualizing the zone of the coarctation by injecting a radiopaque material through a catheter introduced by way of the left axillary artery. Visualization is valuable as a means of avoiding operation in those patients who have an extensive narrowing or in whom the coarctation is not in the region of the descending arch. My co-worker and I attempted to introduce iodopyracet ("diodrast") through a catheter but were unable to inject sufficient contrast medium rapidly enough for visualization. Dr. Earl Miller of the Department of Radiology and I then resorted to retrograde injection of iodopyracet into the left common carotid artery. By this technic we have obtained satisfactory visualization in 14 out of 18 cases. The artery is exposed by a transverse incision above the sternoclavicular articulation and is surrounded by a segment of rubber tubing. After preliminary roentgenograms, the distal carotid is compressed and a needle is inserted under direct vision into the lumen of the artery. The needle is connected by a short segment of tubing to a 50 cc. syringe containing 70 per cent iodopyracet. This solution is injected as rapidly as possible and serial roentgenograms are taken, the first just before completion of the injection. For children an 18 gage needle has been used with the injection of 10 to 25 cc. of solution. In adults we have used a 16 gage needle with 50 cc. of solution. It is important to occlude the carotid artery above the needle during the injection and, after completion of the exposures, to withdraw the iodopyracet solution remaining in the carotid artery, so that none of it reaches the cerebral circulation. Convulsions may otherwise be produced. There were 4 patients in the series of 18 in whom thoracotomy was avoided as a result of visualization of the thoracic aorta. One child had a normal distribution of arteries. In the second patient with classic observations of coarctation of the aorta, the thoracic portion of this vessel was normal. Extensive atresia of the aorta in the lower part of the thorax was visualized in another patient. Finally, the degree of narrowing in the fourth case did not seem to be sufficient to warrant operation. There have been no significant complications from this procedure.

Dr. Robert E. Gross: Dr. Potts mentioned the possibility that the aorta grafts might not hold up for a protracted period of time. That may be true. I would not use a graft on any patient if it is possible to perform a direct anastomosis, because I am sure that the latter is far superior. But it is well to point out that it has been possible to implant grafts in dogs for as long as a year and to find them in excellent condition at the end of such time. It is because of the laboratory groundwork that I have felt justified in trying grafts in a few patients. In reply to Dr. Blalock's question about the age at which it is possible to operate on subjects with coarctation, in the first part of this work I would not have accepted anybody in the upper ages because the technical difficulties increase with age. Like every new procedure, the more experience one gathers, the better the technic becomes, and it is then possible to tackle more and more difficult cases. I am delighted to hear that such good results have been obtained in a man of 41 years. The third point has to do with the adequate support of these patients during a long procedure. One must not allow them to get in a condition of shock or near shock, and then try to pull them back. It is highly important to prevent shock. They must have blood, dextrose and the like, throughout the operation. In order to estimate roughly the blood loss in these patients (blood which is apt to come from the thoracic wall) I take certain precautions. Dry sponges are used; uniform in size, weighing about 8 Gm. They are not moistened when they are put into the chest; when they are discarded a nurse weighs them. There is a scale on which the weighing can be quickly made so that the amount of blood the sponges contain can be quickly ascertained. That figure, plus the amount of blood that is in the suction apparatus bottle on the floor, quickly tells the total amount of blood which has been lost. It is a rough estimate, of course, but it does give one a lead in estimating the amount of blood which must be infused back into the patient.

---

**Rat-Free Alberta.**—To arrive at some explanation as to why Alberta should be rat-free when other parts of North America are infested, a study of various factors has been undertaken. They included physical geography, political geography, vegetation zones, climate, land settlement, land utilization and rat invasion, migration and distribution. The study is not complete but has progressed to a point where preliminary publication appears warranted. Sufficient evidence has been elicited to indicate that a unique opportunity exists in western Canada for a detailed study of the methodology of rat invasions, migration, and distribution. . . . On many occasions during the past forty years rats have been reported in Alberta. And on each occasion the rats were brought in by the railways, but on every occasion they were found and destroyed. The people of Alberta are extremely wide-awake to the rat menace, and are determined to keep Alberta rat-free. However, the true answer to the problem . . . lies not in the interest and enthusiasm of the people of Alberta; it lies in a definite rat-exclusion campaign . . . that should start, not when the rats reach the Alberta border, but now on the west bank of the South Saskatchewan River fifty miles east of the provincial border. The battle that is fought there, if and when it is fought, will determine how long Alberta remains rat-free.—John H. Brown, M.Sc., Alberta: The Only Rat-Free Province in Canada, *Canadian Journal of Public Health,* September 1948.

# HEARTBURN

## A Clinical Study

HENRY J. TUMEN, M.D.
and
EDWIN M. COHN, M.D.
Philadelphia

All physicians encounter patients who have symptoms that are difficult to treat because the mechanisms which produce them are poorly understood. Gastroenterologists deal with a number of such symptoms, among which may be listed not only the many varieties of abdominal pain but also such complaints as belching, flatulence, malodorous breath, a bad taste in the mouth, coated tongue and heartburn. Although these are usually considered to be of minor significance, they may cause great annoyance and, by their resistance to treatment, create troublesome problems for both the patient and the doctor.

Heartburn, the subject of this discussion, is such a symptom of vague causation. Although much has been done to explain its origin, there still exists a need to evaluate the clinical significance of heartburn and of the factors which cause it, so that satisfactory therapy can be planned.

The various studies already carried out in investigating the origin of heartburn need not be reviewed in detail. Reference should be made, however, to the work of Jones.[1] By dilating the esophagus with balloons placed at different levels and by injecting into the esophagus various fluids, he was led to the conclusion that the sensation described as heartburn was caused by an increased state of tension in the muscularis of the esophagus just above the cardiac sphincter, with additional peristalsis in the reverse direction. The relation of local mucosal changes in the lower part of the esophagus to the development of heartburn has not been entirely settled. Alvarez[2] spoke of "sensitization" of the esophagus as contributing to heartburn. The exact nature of this process is not further defined. Babey[3] found that the slow injection into the esophagus of fluids ordinarily considered irritating caused no distress, but that if even bland fluids, such as water or dilute solutions of sodium bicarbonate, were injected rapidly burning distress was produced. This observation argues against mucosal irritation as the mechanism causing heartburn, as does also the speed with which the symptom will often appear and disappear. In all probability, therefore, heartburn is caused by abnormal neuromuscular activity at, or just above, the cardia with alteration in esophageal tonus. This neuromuscular activity may be a response to too rapid dilatation of the esophagus during the act of swallowing, to contraction of the cardiac sphincter because of psychogenic factors or the result of reverse peristaltic waves which begin in the stomach and ascend into the lower part of the esophagus.

Despite the studies which suggest that heartburn is primarily an esophageal symptom, the opinion is still held by some physicians, and it certainly prevails among laymen, that the symptom suggests some organic disturbance of the stomach, duodenum or other portion

of the gastrointestinal tract and also that it is due to "hyperacidity." There is a failure to place the proper emphasis on the production of heartburn by functional esophageal disturbances, caused by faulty eating habits and aerophagia. The frequency with which heartburn is a manifestation of emotional tension is often overlooked. This study was undertaken for the purpose of further dispelling some of the existing misconceptions concerning heartburn. A similar study has already been reported by Alvarez.[2]

### PATIENTS STUDIED

The persons examined for this purpose were a group of 120 patients consecutively encountered in office practice. These patients had been referred to us because of a variety of gastrointestinal disturbances. Since they were unselected in any way, we believe they may be considered fairly typical of patients who consult physicians because of digestive and abdominal distress. Forty-six of these patients, approximately 38 per cent of the total, complained of heartburn; 74 did not have this symptom. The patients with heartburn included 21 men and 25 women, a sex distribution similar to that of the control group, and the age distribution of those with heartburn was likewise not noteworthy. We were not able to find any indication that heartburn occurred more frequently in patients with specific types of body build or habitus.

Among the 46 patients with heartburn, there were 26 in whom the symptom was of sufficient severity to warrant our considering it a major symptom, although in none of these was the heartburn the only reason for seeking medical care. In 20 patients the heartburn was of minor severity, and these persons frequently made mention of the presence of heartburn only after direct questioning.

### PATIENT'S DESCRIPTION OF HEARTBURN

It was often difficult for a patient to describe clearly the type of discomfort with which he suffered and which he called "heartburn." A sensation of burning or heat was the usual description. Adjectives such as "searing" or "acid" were occasionally used. The distress was often localized rather vaguely. The commonest site was behind the lower part of the sternum rather than in the epigastrium. When the patient was asked to point to the area of greatest discomfort, he often placed the entire hand over the lower part of the sternum, indicating an inability sharply to locate the burning sensation. Radiation of the distress only rarely was in a downward direction. When, however, the heartburn was severe, it tended to spread upward along the course of the esophagus, frequently to the pharynx and even to the angles of the jaw. In some instances, the burning sensation was localized entirely to the pharynx, or the pharyngeal distress was so pronounced that substernal burning was mentioned only when it was inquired about specifically. In general, the location of the heartburn did not vary much in the same patient, but it usually recurred in about the same area.

The most frequent time for heartburn to begin was shortly after a meal, particularly a large meal eaten rapidly. The time relation to food intake was inconstant, however, and varied from attack to attack in some patients. Many patients noted no relation to food intake. This was particularly true of those whose heartburn occurred at night and prevented or interrupted sleep. This might happen even though no distress had been present during the day.

### ASSOCIATED SYMPTOMS

Various additional symptoms were associated with heartburn. Occasional patients complained of epigastric pain. Five spoke of epigastric pressure or fulness, synchronous with the substernal burning. The pain differed somewhat from the pain observed in those patients in this group who had such organic gastrointestinal disorders as ulcer, hiatal hernia or cholelithiasis. It was not severe but was usually a sense of distention, indefinitely related to meals, that did not radiate and was usually relieved by belching.

Acid regurgitation occurred in 22, or almost 50 per cent of the patients who had heartburn. In general, this was observed in those whose heartburn was severest, but many patients with severe heartburn did not experience acid regurgitation. The regurgitation was usually described as a bringing up into the pharynx or mouth of intensely sour fluid. Only rarely was the fluid vomited, most patients reswallowing it. Acid regurgitation usually followed severe heartburn that persisted for some time. Occasionally, the ability to regurgitate a few mouthfuls of fluid terminated an attack.

Of the other gastrointestinal symptoms complained of by our patients with heartburn, belching was commonest and was noted in 28. This, of course, is an extremely common symptom. It is interesting to note, however, that it occurred in more than 60 per cent of the patients with heartburn, but was prominent in only 19, roughly 25 per cent, of the 74 patients who did not have heartburn. Detailed studies of the character of the belching of these patients with heartburn indicated that, as in most persons, the eructations were largely the result of factors which produced air swallowing. The belching usually was habitual, often explosive and worse during periods of nervous tension. Many of the patients noted that both symptoms, belching and heartburn, were aggravated by the same factors, such as hurried eating, emotional strain and anxiety. Only rarely could statements be elicited to indicate that the act of belching induced heartburn or that belching relieved heartburn.

Nausea was also fairly common in these patients, being an additional symptom in 17, or about 37 per cent. The nausea tended to occur in waves and to be worse during periods of severe heartburn. Actual vomiting was much less common, being complained of by 7, or about 15 per cent of the patients. The vomiting generally consisted of recently ingested food and did not always relieve the heartburn.

Colonic symptoms, severe constipation and diarrhea, were complained of with a little less frequency by those patients with heartburn than by those without heartburn. These existed in roughly 47 per cent of the patients with heartburn, 16 having constipation and 5 diarrhea, whereas 58 per cent of the control group had these symptoms, 32 being constipated and 11 having diarrhea. The differences in the rates of occurrence of these colonic symptoms did not seem significant. If any conclusion can be drawn from this comparison between the two groups, it would seem to indicate that the functional colonic disorders, which were largely responsible for the constipation or diarrhea of almost all of the patients in whom they were observed, do not influence the incidence of heartburn.

### FACTORS WHICH PRECIPITATED OR AGGRAVATED HEARTBURN

Nervous tension was apparently the outstandin immediate cause of heartburn in this group of patien Thirty-four of the 46 patients, almost 75 per recognized that their heartburn was worse during periods of emotional strain. They could frequently cite specific situations in which their heartburn had been troublesome. This point will be discussed in greater detail in speaking again of the causation of heartburn, but, as we reviewed these patients, we were increasingly conscious of the frequent close relation between annoyance, nervous tension or anger and the appearance of severe heartburn.

Fatigue was also recognized as an aggravating factor by 8 of the patients with heartburn. They knew that hard work and long hours increased the frequency and severity of their substernal burning. How often fatigue was responsible for increased nervous tension and initiation of emotional disturbance could not be stated with accuracy.

Specific foods were considered as causing heartburn by 16, almost one third of these patients. The offending foods were usually mentioned as groups of foods, rather than individual substances. Thus, sensitivity to such classes of foods as "fats," "fried foods," "spices," "gravies" and "sweets" was often mentioned by patients, although a number did name additional individual foods which also caused distress. Coffee, onions, cabbage, chocolate and orange were outstanding examples of these. These foods, which apparently caused or aggravated heartburn, are, of course, often thought to be the sources of discomfort to many patients. It was interesting to observe, however, that of the control group of 74 patients without heartburn, only 10 believed that fats, spices, greasy foods and the like disagreed with them. The symptoms produced in these latter patients by the offending foods were generally described as epigastric pressure, discomfort, belching and flatulence, symptoms which might also occur in association with heartburn when this was caused by these foods. It is difficult to be certain of the mechanism by which the foods mentioned precipitated heartburn. It is possible that alterations in gastrointestinal motility resulted in reverse peristalsis and consequent pressure changes within the esophagus. There is still no clear explanation of why and how foods "disagree' with various persons.

The sensitivity to foods just mentioned seemed entirely different from food allergies. Specific allergies to foods were noted in only 2 of the 46 patients with heartburn. Both were sensitive to chocolate, and, in addition, 1 was also sensitive to peanuts and onions. The taking of these foods produced heartburn, as did the taking of such substances as fats and sweets. There were, however, 9 patients in the group of 74 without heartburn who had definite allergies to a large variety of foods. Ingestion of known allergens induced such digestive symptoms as abdominal cramps, diarrhea, nausea and vomiting and aphthous ulcers in the mouth, but did not cause heartburn in these persons. It is difficult to conclude, therefore, that heartburn is a symptom of allergic origin.

The relation of heartburn to the act of eating, without reference to the type of food taken, was not a constant one. Thirty-four patients stated that their heartburn occurred after meals and could be relieved by fasting. Twelve others felt worse when hungry and were relieved somewhat by food. The relationships between food intake and heartburn varied, however, from time to time. Many of the patients recognized that their manner of eating induced heartburn and that they were more likely to suffer when they ate too fast or ate when excited.

Six of these patients recognized that smoking made their heartburn worse, and in 2 heartburn was aggravated by alcohol. The number of drinkers in the group, however, was so small that no conclusions regarding the influence of liquor is justified.

Six of the patients believed that their heartburn was worse during periods of constipation, and at such times the heartburn was associated with other vague symptoms, such as flatulence and belching. It was occasionally possible for these patients to obtain relief of their heartburn by the use of a laxative or an enema.

In general, posture did not seem to have much influence on the occurrence of heartburn. Body position was of greatest influence in those patients who had some defect in the region of the cardia. The 8 patients with heartburn who had hiatal hernia noted definitely that lying down or bending over increased the heartburn and that the symptom was worse at night. This was also the case in 1 man whose studies demonstrated what was considered to be a "relaxed cardia." Of the other patients who had no structural changes about the lower part of the esophagus, only 1 had heartburn that was worse at night or while the patient was recumbent. One other patient, in contrast, could relieve her heartburn by lying down.

### FACTORS WHICH RELIEVED HEARTBURN

Patients suffering with heartburn try various methods for relief of this symptom. Among our patients, the commonest form of self treatment was the taking of antacids, of which sodium bicarbonate was used most widely. Twenty-one of the 46 patients could ease their heartburn by taking antacid medication. The majority had used soda at various times, and considered this to be of specific benefit, but all varieties of proprietary antacids—including combinations of bismuth subcarbonate and magnesium trisilicate with and without soda, as well as aluminum hydroxide preparations—were tried. These were used with variable success by different patients, and many of them selected time-tested favorites on which they could usually rely for relief. Although numerous antacids that did not contain soda seemed helpful, many of these were chosen in preference to soda for reasons of convenience or because it was thought that the frequent taking of soda might be harmful. Most of the patients believed that, if soda could be taken, this afforded relief more rapidly. Relief by soda was usually ascribed by the patient to the belching it caused, but belching was not essential to relief by antacids, since many of these gave relief without causing eructations.

There was no consistent relation between the relief given by antacids and the amount of hydrochloric acid in the stomach. A few patients in this group whose acid levels were low also used antacids to relieve heartburn, and apparently successfully. We have seen 1 patient, not included in this group, who suffered with heartburn even though his stomach had been entirely removed because of a gastric malignant condition. This man also occasionally took soda and obtained relief from it.

It must be noted that 25 of these 46 patients were not able to relieve their heartburn by taking antacids. This would seem further to indicate a lack of relation between the occurrence of heartburn and the amount of acid in the stomach.

The maner in which alkalies relieve heartburn is still uncertain. In the case of soda the relief may result from changes in the esophageal tonus which come after induced belching. The other antacids may be palliative because they alter intragastric tonus and so, indirectly, relieve pressure within the lower part of the esophagus.

The origin of heartburn in altered esophageal tonus is also suggested by the fact that many patients with heartburn get relief if they can belch. This was true of 17 of the 46 patients. These patients were helped by belching induced by the taking of soda, carbonated beverages or large amounts of fluids. Often, however, after relief was observed following belching that was apparently spontaneous, patients learned to make themselves belch and became aerophagic as a result. The taking of food relieved the heartburn of 12 of these patients. Usually the patients did not make a practice of eating in order to obtain relief, but a few patients acquired the habit of taking milk just as patients with ulcer learn to do this to relieve their pain.

### RELATION OF HEARTBURN TO ORGANIC GASTROINTESTINAL DISEASE

To enable us to decide whether the presence of organic gastrointestinal disease led to the development of the symptom of heartburn, comparison was made of the final diagnoses established in the 46 patients with heartburn and the 74 patients without this symptom. The results are listed in the table.

*Incidence of Gastrointestinal Diseases in Patients With and Without Heartburn* *

| | Heartburn, No. of Patients | No Heartburn, No. of Patients |
|---|---|---|
| No significant gastrointestinal disease... | 15 | 35 |
| Ulcer .................................... | 7 (duodenal)<br>1 (gastric) | 23 (duodenal)<br>2 (gastric) |
| Cholelithiasis ........................... | 6 | 4 |
| Gastritis (gastroscopic diagnosis)....... | 3 | 1 |
| Irritable colon syndrome................ | 11 | 18 |
| Hiatal hernia ............................ | 8 | 3 |
| Food allergies ........................... | 3 | 9 |
| "Cardiospasm" ........................... | .. | 2 |
| Gastric carcinoma ....................... | .. | 3 |
| Ulcerative colitis ........................ | 1 | 1 |
| Carcinoma of colon...................... | .. | 3 |
| Acute hepatitis .......................... | .. | 3 |
| Previous gastric resection............... | .. | 1 |

* There were 46 patients with heartburn and 74 without heartburn; many patients had multiple diagnoses.

In both groups there were significant numbers of patients who did not have definite gastrointestinal disease. These were patients who had abdominal or digestive symptoms of purely "functional" origin or secondary to disease outside the gastrointestinal tract. It is important to note, however, that in one third of the patients with heartburn detailed gastrointestinal investigation did not reveal organic disease of the digestive organs.

Ulcer, either gastric or duodenal, existed in 8 of the 46 patients with heartburn (17.4 per cent) and in 25 (33.7 per cent) of those without heartburn. Of the 33 patients with ulcer encountered in the entire group of 120 studied, only 8, or 24.2 per cent, complained of heartburn. In those patients with ulcer who had heartburn, no definite relation could be traced between activity of the ulcer, as indicated by characteristic pain or roentgen evidence of this, and the occurrence of heartburn. When patients first presented themselves with active ulcer disease they sometimes stated that the heartburn and the epigastric pain occurred simultaneously. Questioning would usually indicate, however, that what was meant was that both symptoms often occurred at the same time in relation to food intake, but that they really were independent of each other, the heartburn not undergoing seasonal or spontaneous remissions with the pain and usually persisting long after therapy had completely relieved true ulcer pain. Continued observation of patients with ulcer having heartburn indicated that pain and other indications of ulcer activity yielded to therapy much more readily than did the heartburn. Our experience was, therefore, in accord with that of Alvarez.[2]

Heartburn was not found to be a symptom of ulcer, and when it was complained of by patients with ulcer it seemed purely an extraneous symptom.

In the total group of 120 patients there were 29 in whom the final diagnosis of "irritable colon" syndrome was made. This diagnosis is a rather loose one and was based on the presence of either constipation or diarrhea as a major complaint, the presence of distress in the lower part of the abdomen related in its occurrence to bowel function, absence of organic disease of the colon and roentgen demonstration of disturbed colonic motility and tonus. It was frequently difficult to decide whether patients with these symptoms were best considered as having simply a "functional gastrointestinal disorder" or whether they should be placed in a more closely defined category. Preponderance of colonic symptoms was usually the criterion for deciding on the diagnosis of "irritable colon."

In any case, heartburn was a symptom in 11 of the 29 patients classified as having an irritable colon. The incidence of heartburn was roughly the same as the incidence of heartburn in the entire group of 120 patients. Eighteen patients with irritable colon did not have heartburn. Patients with irritable colon and heartburn did not observe any relation between the latter and their bowel symptoms. Our experience indicates, therefore, that the mechanism causing heartburn was independent of that responsible for the irritable colon syndrome.

There was no indication that heartburn was a significant symptom of cholelithiasis. Although it occurred in 6 of the 10 patients with gallstones, there was no relation between the heartburn and the major attacks of biliary pain. Heartburn, when it existed, seemed to be a purely coincidental complaint. None of the patients in this group, however, was subjected to cholecystectomy, so that the effect of the removal of the gallbladder on the symptom of heartburn cannot be stated.

Hiatal hernia was the only organic condition among these patients with which heartburn seemed to be associated with outstanding frequency. Of the 11 patients with hiatal hernia, 8 complained of heartburn as a major symptom. They also suffered with abdominal and substernal discomfort. In these patients the heartburn usually occurred after a full meal and was also nocturnal, apparently induced by lying down and relieved by the upright position. Similar description of symptoms was made by 1 patient with "relaxed cardia." If heartburn is due to disturbed function of the lower part of the esophagus, its frequent occurrence in patients with hiatal hernia is not surprising.

Gastric analyses were done in 31 of the 46 patients with heartburn. Free acid was low or absent in 4, normal in 15 and above normal in 11. Fifty-two of the 74 patients without heartburn had gastric analyses. Low or absent acid was observed in 11, normal acid levels in 25 and hyperacidity in 16. These observations, similar to those already observed by others, show once more the lack of any dependence of heartburn on the degree of gastric acidity and the lack of relation of heartburn to "hyperacidity."

In general, therefore, review of the diagnoses established in patients with and without heartburn did not indicate that heartburn occurs because of organic gastrointestinal disease. Heartburn was not observed to be a symptom suggesting the presence or absence of any specific gastrointestinal disorder, with the possible exception of hiatal hernia. The existence of heartburn, therefore, is probably not due primarily to any organic change within the gastrointestinal tract.

## CAUSES OF HEARTBURN

Heartburn is not due to any organic gastrointestinal disease. It is not caused by excessive gastric acidity. Investigations, such as those of Jones,[1] indicate that changes in the tonus of the esophagus probably produce this symptom. How are these changes brought about in patients who suffer with heartburn?

Discussions with these 46 patients indicated that many patients with heartburn have what can be described as bad eating habits. Twenty of the 46 admitted that they were extremely fast eaters, who took their meals in as short a time as possible, either because of long-standing custom, often familial, or because of the supposed necessity for speedy return to work. Many of the patients consumed large amounts of fluids with their meals, often taking two or three glasses in rapid succession. Carbonated drinks were taken freely by a few of the patients. About half of these patients were aerophagic, but it was difficult to tell whether this symptom had preceded or followed the appearance of heartburn. A number of the patients had apparently acquired the belching habit in an attempt to relieve heartburn. Gum chewing, with its resultant constant swallowing and repeated belching, was a frequent habit. In fact, most of these patients were doing various things which could conceivably lead to overdistention of the stomach, reversal of gastric peristaltic waves, with regurgitation of air and fluids into the lower part of the esophagus, and consequent increase in the activity of the lower part of the esophagus. If heartburn is considered to be a result of altered neuromuscular activity within the lower part of the esophagus, ample background seemed to exist for this in these patients. Faulty eating habits are, of course, fairly common, but questioning of the 74 patients without heartburn revealed that fast eating, gulping of food, washing it down with large quantities of water and the like were practiced by only 9 persons in that group. This further suggests the role which poor eating habits may play in the evolution of heartburn.

In addition to the factors just mentioned, attention should be called to the personality makeup of some of the patients who had heartburn. Among the 46 with heartburn there were 8 men who can be described as extremely tense, quick to anger, resentful and easily offended. They seemed rather rigid, a little difficult to get along with and critical of minor faults in others. As some of them said, they "got burnt up easily." Few of them had ready insight into their reactions of other persons. They had numerous prejudices and suspicions that kept them on guard and made relaxation difficult. Occasional patients seemed almost masochistic in their relations with other persons. One patient described a situation in which he permitted an employee to continue to do something that was obviously incorrect "just to see how long he thought he could get away with it." During the entire time that these circumstances existed the patient was extremely tense and he continued to have heartburn of great severity, resistant to all attempts at relief. This increased each time he discussed the employee's wrongdoing or even thought about it. With great difficulty he was finally persuaded to order the employee to correct the fault. There was significant decrease in the patient's tension, and the heartburn promptly disappeared. The patient was referred for psychiatric care because of repetition of episodes of this type. Psychotherapy gave him insight into his problems and helped him acquire ability to handle them. Coincident with this, his heartburn disappeared without significant change in diet and without medication. Formal psychiatric care was of benefit in the treatment of 2 additional patients.

Unfortunately, it was not possible to make fluoroscopic studies of these patients during periods of emotional stress to visualize what changes, if any, these produced in esophageal caliber and motor activity. Studies have been reported by Faulkner,[4] however, which demonstrated by direct esophagoscopic examination that esophageal spasm can be increased and the esophageal lumen narrowed or closed by suggestions producing destructive emotions, such as grief, anger, apprehension, anxiety and fear.

Heartburn may, therefore, occasionally be a symptom of psychosomatic origin. It may be what can well be termed "a monosymptomatic neurosis," a somatic reference of psychogenic disturbances, although why the esophagus is selected as the organ of reference is difficult to state without much deeper psychiatric investigation than these patients had.

Here again definite differences were found between those patients who did and those who did not suffer with heartburn. Among the 74 patients without heartburn, there were many who could easily be considered "neurotic"—patients who were worrisome and anxious about their health or about various situations and problems, introspective, dependent and not sure of themselves. These characteristics were not uncommon among those with "irritable colon," but most of these patients were not resentful, did not anger easily, were eager to establish satisfactory contact with the physician and fairly easily reached an understanding of the problems which troubled them. In fact, of the 74 patients who did not have heartburn, only 1 was found whose personality pattern was similar to that observed in some of the persons with intractable heartburn. We believe, therefore, that heartburn may occasionally be a neurotic manifestation and that in these circumstances its relief may require adequate psychiatric study and therapy.

## TREATMENT

The treatment of a symptom such as heartburn is not so much a matter of single specific measures as of the outlining of a general program which will remove the cause, if any can be found, and allay the irritability of the esophagus and stomach, as well as help the patient understand the nature of his problem so that he can aid in its correction.

Review of the course of the 46 patients who had heartburn indicates that, in general, drugs were of little use in the treatment of the symptom and were probably not essential for its relief. Antacids were

---

4. Faulkner, W. B.: Objective Esophageal Changes Due to Psychic Factors, Am. J. M. Sc. 200: 796, 1940.

prescribed, but only to 5 patients. These were patients with peptic ulcer who had active ulcer symptoms and were treated by means of diet, sedatives, belladonna and either aluminum hydroxide or magnesium trisilicate. It is difficult to ascribe the relief of heartburn in these circumstances to the use of antacids.

Belladonna, without antacids, was used in 5 additional patients without ulcer. Here again, it is difficult to be certain regarding the benefit obtained, since general measures, to be discussed later, were also used. It was felt, however, that the use of belladonna in a dose large enough to obtain physiologic effect contributed to the relief obtained. Mild sedatives were helpful in the initial stages of therapy and were usually liberally used. An occasional patient was given neostigmine, as suggested by Williams[5] in the treatment of heartburn of pregnancy. This drug was not of apparent benefit, but it was used too seldom to permit one's judging its value.

Aside from the dietary regulation necessary for the treatment of ulcer, when this was present, the diet of these patients was changed only to the extent of eliminating foods which their own experience had indicated would cause discomfort. As noted already, these were usually such items as fried foods and spices. Some patients were able to resume judicious use of these after their heartburn had been relieved, but others found it necessary to restrict the use of certain specific foods indefinitely. The relief of constipation, largely by the instruction in the development of hygienic bowel habits, was incorporated in the general program, when this was indicated. Although 10 patients stated that some decrease in heartburn occurred when normal bowel movements were obtained, it was difficult to be certain regarding the importance of this.

It is our impression that the most significant phase of the treatment of heartburn was discussion with the patient regarding the nature of his problem, explanation of its functional nature, education in proper eating habits and, when necessary, adequate psychotherapy. Our records indicate that this approach, which may be labeled as "therapeutic discussion," was not only helpful in 34 of the patients treated but that it made the major contribution to relief. The program of education in eating habits included instructions concerning reduced speed of eating, adequate time for meals, the proper spacing of meals, discouragement of the practice of getting most of the day's food at one large meal and the avoidance of excessive fluids with meals. The patients were also instructed in methods of stopping air swallowing by adding to the aforementioned instructions avoidance of carbonated drinks and chewing gum and suggestions that they make a voluntary effort to stop belching. The educational program was well accepted by most patients.

Psychotherapy of a very superficial type formed part of the general program. It usually consisted of explanations concerning the effects of tension, discussion with the patient of various situations causing emotional disturbances and the encouragement of free expressions of personal problems. Those patients with personality problems of a deeper variety were encouraged to seek psychiatric care. This was obtained by 3 of the patients with definite benefit.

In general, the results of this therapeutic program were gratifying. All of the 46 patients obtained definite relief, although some had recurrences of heartburn with extreme nervous tension. We believe, however, that recognition of the functional nature of heartburn permits the institution of therapy which will be satisfactory in the majority of patients who have this symptom.

### SUMMARY AND CONCLUSIONS

One hundred and twenty patients were studied to determine the incidence of heartburn and its clinical features. Among these patients, 46, or about 38 per cent, had heartburn. In 26, heartburn was severe enough to be considered a major symptom.

Heartburn was often described with difficulty by patients but was usually a burning discomfort diffusely localized behind the lower part of the sternum, often radiating upward along the course of the esophagus. Heartburn was often associated with other gastrointestinal symptoms, of which acid regurgitation, belching, nausea and epigastric pressure were most troublesome.

Nervous tension was apparently the commonest immediate precipitating cause of heartburn. Sensitivity to certain foods—such as fats and spicy foods—also frequently induced heartburn, but the role of foods in this respect was apparently not due to specific allergy. Hiatal hernia was the only organic gastrointestinal disease encountered in these patients in which heartburn seemed to be a specific symptom. Otherwise, there was no relation between heartburn and gastrointestinal disease. Heartburn was not a symptom of ulcer. It was not dependent on the degree of gastric acidity. Heartburn is probably produced by alterations in the tonus of the lower part of the esophagus. In these patients this seemed most frequently induced by faulty eating habits, but in 8 of the 46 patients with heartburn the symptom was possibly a psychosomatic manifestation and an expression of tension and emotional disturbance.

The therapy of heartburn should be directed toward the relief of the factors which have produced the underlying esophageal functional disturbance. This usually necessitates correction of poor eating habits. In those patients in whom the symptom is of psychogenic origin, appropriate psychotherapy is indicated.

### ABSTRACT OF DISCUSSION

Dr. David J. Sandweiss, Detroit: Sugarman and I studied 50 consecutive private patients who complained of or admitted heartburn; in addition, my co-workers and I studied the records of 50 patients selected at random in the outpatient department. Of the 100 patients 7 per cent had esophageal pathologic conditions, 3 per cent gastric ulcer, 47 per cent duodenal disease, 12 per cent colon disturbances and 13 per cent biliary tract disease. Two per cent of our patients attributed their heartburn to smoking or chewing tobacco. Five per cent were found to have nongastrointestinal condition (1 case of early pregnancy, 1 of bronchiectasis, 1 of malignant hypertension and 2 with coronary spasm). In 11 per cent of our patients no pathologic condition was found (though 3 of these 11 patients were found to have ventral or inguinal hernia). With regard to the clinical significance of heartburn, Dr. Tumen infers that functional states are the commonest causes of heartburn since 74 per cent of his patients responded to discussion therapy. There is no doubt that many of the patients in our series have tensional states in addition to the disease found. Not only may one list all cases in which there was "no pathologic conditions found" as "tension cases" but also the group with irritable colon and several others. There are many who would classify all patients with duodenal ulcer as falling in this group. The question might be asked, therefore, whether the tensional state or the disease found is responsible for this symptom. I do not believe that this question can be answered definitely with the data presently at hand. Until otherwise proved I am inclined to incriminate the gastric or duodenal ulcer, the biliary tract disease, the irritable colon and the like. One may, however, definitely say that while heartburn in some patients may be a psychosomatic manifestation and may respond to "therapeutic discussion" when no organic disease is found, heartburn in general should be looked on as a symptom of major importance, since more frequently than not organic disease will be found which requires a great deal more attention than discussion therapy.

[5] Williams, N. H.: Variable Significance of Heartburn, Am. J. Obst. & Gynec. 42: 814, 1941.

Dr. John H. Fitzgibbon, Portland, Ore.: We are living in a psychosomatic age. While recognizing the necessity for emphasis, I believe that organic conditions are overlooked frequently because of overemphasis of the psychosomatic. We had a discussion this morning of hiatus hernia, which is commonly acompanied by heartburn. I should like to add a few remarks in regard to the endoscopic diagnosis of hiatus hernia. In the short esophagus, there is an organic condition in which regurgitation is an outstanding symptom. Stenosis of the cardia frequently results and not uncommonly is associated with ulceration. The patients may complain of heartburn for many years. Without proper examination the condition is usually overlooked. In the short esophagus, the esophagoscope is of more value than the gastroscope, giving a direct view of the cardia. Unless the stricture is too tight, gastric mucosa can usually be seen beyond the cardia. Twelve years ago my co-workers and I began the gastroscopic examination of patients suspected of having hiatus hernia. Several were discovered that had been missed entirely by roentgen examination. We soon found that roentgen examinations were more effective if the patient were examined in the gastroscopic or left-sided position. On deep inspiration part of the upper end of the stomach is sucked through the hiatus into the thorax. In that position the barium preparation is regurgitated more easily. In the gastroscopic appearance of typical hiatus hernia, there is a constriction at the level of the diaphragm and gastric mucosa is seen above and below. Not all hiatus hernias are easily demonstrated. At times erosions may be seen. In 1 case of sliding hernia, I observed hypertrophic gastritis at the level of the diaphragm. In addition to this organic condition, one must consider as a cause of heartburn the wide hiatus which has been mentioned previously. Heartburn is an indefinite term. The patient may be talking about something other than what the physician has in mind. It sometimes accompanies achlorhydria as well as acid gastric secretion. The patient may experience a different sensation that you or I might accept as heartburn. In persons who are regurgitators, who have complained of heartburn over a period of years, organic lesions of the esophagus may develop. A boy of 18 complained of heartburn for several years. He was placed on a diet and liquids were reduced. Eighteen years later he was still complaining of heartburn plus distress on swallowing. At that time a narrowing of the middle part of the esophagus was observed roentgenographically. A ring of erosions and definite constriction was seen through the esophagoscope. I believe that this was a case of regurgitation which caused erosions of the esophagus. I would emphasize the need for adequate search for all possible organic factors in cases of heartburn.

Dr. Anthony Bassler, New York: There seems to be a significant note of organic disease brought into this subject. Two or three years ago one of my associates carried out an extensive study on hearburn (which has not been published). We felt that true heartburn was most often produced by a derangement within the stomach rather than in the lower portion of the esophagus, a derangement between the acid fundus end and the more alkaline pyloric end. There is in this functional disturbance (usually brought about by one's taking adverse foods or fluids) a condition of affairs in which the acidity runs high because of neutralization deficiency in the pyloric end. We also in that connection made mucous studies, in lipozyme particularly, and we were able to prove that so far as the effect of lipozyme on the stomach was concerned, it was not nearly so distinct as it was in the intestinal canal.

Dr. Sidney A. Portis, Chicago: It is presupposed that in heartburn a very thorough organic study will be made. No one is going to dismiss heartburn as a simple symptom without that approach to the patient. From the so-called functional disturbances, and disturbed physiologic balance, a large group of these patients may have dyskinesia of the gallbladder, which in turn produces a reverse peristalsis of the stomach. In answer to Dr. Fitzgibbon's remarks that we in gastrointestinal medicine are taking the easier path and sliding out under the influences of the psychosomatic approach, may I call attention to the fact that heartburn may be conversion hysteria *in many patients?* I have seen heartburn in patients with histamine-free achlorhydria. One cannot dismiss this question of heartburn in patients in whom there are no organic observations, and all of you are well acquainted with the fact that in these patients symptomatic relief is difficult to obtain. Too little is understood about the mechanisms of conversion hysteria in the esophagus. We do know that it is of a definite clinical significance. When esophagoscopic, gastroscopic and roentgenologic observation has revealed no disease, the physician should consider that there may be a functional disturbance which originates in the emotional centers and is projected into that portion of the gastrointestinal tract. Many patients have symptomatic disturbances of the gastrointestinal tract that do not respond to ordinary methods of investigation. If the physician is not certain about the organic phase, the patient certainly should be interrogated as to the possible source of trouble, because that trouble is just as real, and the patient is just as sick as the patient who comes in for duodenal ulcer or any other organic disease.

Dr. Hyman I. Goldstein, Camden, N. J.: Diocles (350 B. C.) described heartburn as "acid, 'acrid,' and painful eructations." Galen (130-201 A. D.) quoted Diocles, the symptoms having been given just as they are today. Sir Gilbert Blane (1749-1834), a naval physician, on March 1, 1796, one hundred and fifty-two years ago, discussed the subject and advised treatment with milk of magnesia, mild alkalies and calcareous earths, to correct high gastric acidity, to prevent serious gastric disease and to relieve the patient of these complaints.

Dr. Henry J. Tumen, Philadelphia: Dr. Cohn and I do not believe that heartburn is a new problem. Since, however, we are what might be called general practitioners of gastroenterology, we daily see patients who have symptoms difficult to relieve because of the unsatisfactory state of our knowledge of the mechanisms causing them. Heartburn is a symptom of this type. We are convinced that heartburn is not caused by organic gastrointestinal disease. Dr. Sandweiss has listed the various organic diseases observed in his patients who had heartburn. We believe that such observations are coincidental and that the diseases found do not cause the heartburn. Although the incidence of heartburn varies, we wished to stress the relative frequency of its occurrence and to emphasize its "functional" nature and its importance as a psychosomatic manifestation. It is obvious that patients with heartburn should be studied for the purpose of discovering any organic diseases which they may have, such as ulcer or gallstones. If these are found, they must be treated, but heartburn is not likely to be relieved by one's focusing the entire attention on an organic disorder. Dr. Sandweiss is correct in emphasizing the need for additional studies to explain the mechanism causing the heartburn. Little has been done to investigate the reaction of the esophagus to emotional factors. Some years ago Faulkner reported on the esophagoscopic visualization of responses of the esophagus to psychic trauma. Such studies should be repeated, and there should also be investigations of the esophagus to determine changes in its tonus and motility in relation to the existence of heartburn. Our own study is a crude one, based entirely on clinical impressions. It has seemed important to us, however, to emphasize what we believe to be the essential cause of heartburn. A therapeutic approach based solely on an "organic viewpoint" will often fail to relieve the patient *suffering with this troublesome symptom.*

# CARCINOMA CELLS IN PROSTATIC SECRETIONS

DONALD D. ALBERS, M.D.
JOHN R. McDONALD, M.D.
and
GERSHOM J. THOMPSON, M.D.
Rochester, Minn.

Cancer of the prostate accounts for 8,000 deaths each year in the United States and is clinically the second commonest cancer in men.[1] The condition is usually detected with the examining finger,[2] a procedure which is rather accurate for well advanced carcinoma but which is not accurate for early questionable lesions. Colby[3] found the impression gained from digital examination to be in error in 8 of 34 patients with early lesions who underwent radical perineal prostatectomy. McHeffey[4] found experienced urologists 88 per cent accurate when they made the clinical diagnosis of prostatic cancer in patients who needed surgical treatment for urinary obstruction. To detect early malignant lesions with the examining finger presupposes that all carcinomas arise in the posterior regions of the gland. Kahler,[5] in a detailed pathologic study of malignant lesions of the prostate, noted more instances of carcinoma arising in the anterior and lateral lobes than in the posterior lobe.

Several methods of biopsy are available for the diagnosis of prostatic carcinoma, but they all leave much to be desired. Biochemical methods for the diagnosis of carcinoma of the prostate have not proved to be of much value for early diagnosis. The elevation of acid phosphatase appears in few cases without evidence of osseous metastasis.[6] The excretion of the 17-ketosteroids, which is linked with production of testosterone and secondary sex characteristics, has been observed to be unaltered in carcinoma of the prostate.[7]

The cytologic diagnosis of carcinoma based on the examination of secretions has in recent years become popular, since the work of Papanicolaou[8] on vaginal secretions. Cellular diagnostic procedures have become established in some laboratories in the diagnosis of carcinoma of the uterus[9] and lungs.[10] The diagnosis of malignant disease from a study of secretions is not new, and in the urinary tract a case of tumor of the bladder in which the diagnosis was made by examination of the urine was reported by Sanders[11] in 1864. Until recently, the most extensive work on the diagnosis of malignant disease of the urinary tract on the basis of a study of the urine was published by Quensel[12] in 1918; in this work he included cases of tumor of the kidney, bladder and renal pelvis, with illustrations. More recently, Papanicolaou and Marshall,[13] Papanicolaou[14] and Daut[15] have reported finding cells of prostatic carcinoma in the urine.

Review of the literature failed to disclose any mention of a study of malignant cells in prostatic secretions previous to the report in 1931 by Mulholland.[16] Mulholland studied a series of patients who were not suspected of having a malignant disease and another series of patients with clinically malignant lesions of the prostate. He observed abnormal cells in 77 per cent of the second group but refrained from calling them carcinoma cells.

Herbut and Lubin[17] in 1947 published the second article to appear in the literature dealing with malignant cells in prostatic secretion. They used the Papanicolaou technic of staining and obtained the specimens by the standard method of prostatic massage. Prostatic secretions from 100 patients were examined, and a diagnosis of carcinoma of the prostate was rendered 17 times. The diagnosis was confirmed histologically in 10 of these cases. In only 1 case was the diagnosis made when the disease was not evident clinically, but in this case the diagnosis was not proved histologically. These authors set forth two criteria for the diagnosis of carcinoma from examination of prostatic secretions: (1) the presence of an unusual number of multicolored pavement cells and (2) the presence of cancer cells. Emphasis was placed on the staining qualities of the cytoplasm, and in 1 case the diagnosis was made on the basis of the multicolored pavement cells without cancer cells being present.

Further study on the diagnosis of prostatic carcinoma based on examination of the prostatic secretions seems justified because of the present inadequate methods of biopsy, the inaccuracy of clinical diagnosis and the chance that the results of study of the prostatic secretions may permit an earlier diagnosis to be made. The importance of early diagnosis depends at present somewhat on whether one believes in radical perineal prostatectomy or not, but it is felt that, were earlier more accurate diagnosis possible, such procedure might enjoy greater application. With the increase in life expectancy (twenty years since 1900),[18] carcinoma of the prostate is expected to be an ever increasing problem.

## OBJECT OF THE STUDY

This study was conducted to demonstrate further that carcinoma of the prostate can be diagnosed by

examination of prostatic secretions. Other information sought for concerned the accuracy of this test in regard to prostatic carcinoma in general and well differentiated prostatic carcinoma in particular, the criteria for the diagnosis based on a study of the prostatic secretions, the diagnosis of prostatic malignancy before it is clinically evident and the components of prostatic secretions which might be confused with malignant cells.

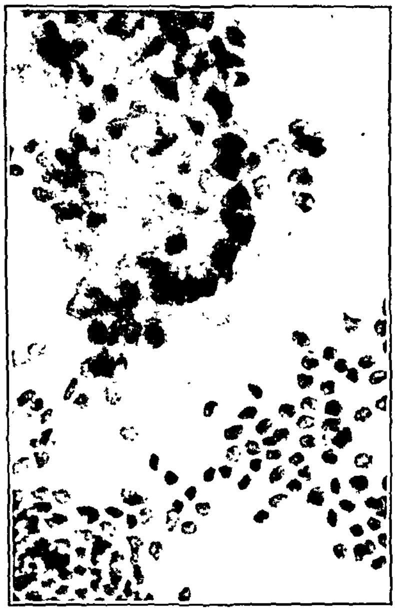

Fig. 1.—Smear made by expressing tissue from a prostatic carcinoma showing a comparison between benign and malignant prostatic epithelial cells (hematoxylin and eosin × 430).

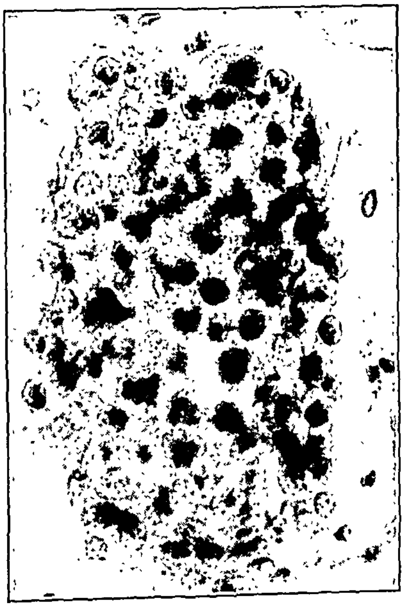

Fig. 2.—Clump of carcinoma cells in the prostatic secretion of a patient with a poorly differentiated carcinoma. The mitotic figure may be noted (hematoxylin and eosin ×430).

## METHODS AND MATERIALS

*Technic of Making Smears and Fixing.*—Prostatic secretions were obtained by the customary method of prostatic massage, and a drop of secretion was placed near the end of each slide. This was spread in a circular manner with an applicator. Before drying, the slides were immersed in an alcohol-ether mixture (equal parts of 95 per cent alcohol and ether) in Coplin jars. An attempt was made to prepare at least four slides for each patient. These slides were left in the fixative for not less than thirty minutes.

*Staining.*—The slides were passed through three strengths of alcohol (80, 70 and 50 per cent) and then through tap water. They were then either allowed to dry or were started on the rest of the staining procedure immediately. The technic used was a routine hematoxylin-eosin method with certain shortcuts,[10b] but any routine hematoxylin-eosin technic should be satisfactory after some experience has been obtained.

*Examination of Slides.*—All slides from each patient were examined at 100 power, the mechanical stage being used to assure complete coverage. Any suspicious cell was examined under 430 power for identification and, when considered worthy, was marked with ink for further reference. In general, it took about twenty to thirty minutes to cover adequately four slides, particularly if no malignant cells were seen. When malignant cells were present, they were usually found on the first slide, and sometimes the diagnosis could be made in a few seconds.

*Secretions Studied.*—Initially, in order that acquaintance with the prostatic epithelial cells in secretions of both benign and malignant prostates might be had, smears made by expressing, on slides, pieces of prostatic tissue removed at transurethral resection were studied. In all, about thirty slides were studied, comprising benign conditions and the four grades of cancer of the prostate (Broders' classification). Then the prostatic secretions from two series of cases were studied. Series 1 consisted of 100 patients with clinically benign prostatic hypertrophy, all scheduled for transurethral resection, and series 2 comprised 41 patients with clinically malignant disease of the prostate, most of whom had obstructive symptoms and were scheduled for operation. Only one specimen was taken in each case.

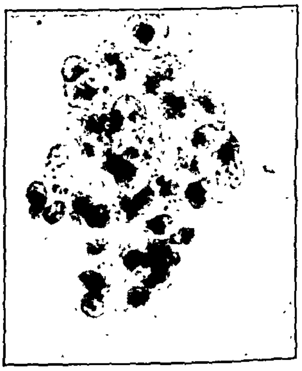

Fig. 3.—Clump of carcinoma cells in the secretion of a case of nonclinical prostatic carcinoma in which the cells are well differentiated (grade 2) (hematoxylin in eosin × 430).

## OBSERVATIONS AND RESULTS

*Characteristics of Secretions* (figs. 1 through 5).—Benign secretions contained few cells except when prostatitis was present. The cells were recognized as polymorphonuclear leukocytes, large mononuclear cells (apparently blood monocytes) and squamous, transitional and prostatic epithelial cells. The leukocytes usually predominated. Prostatic epithelial cells were recognized easily when they were in clusters but with difficulty when they appeared as single cells. Clusters of more than 5 prostatic cells were uncommon and mitotic figures were not seen in any of the proved benign secretions.

Malignant secretions (figs. 2, 3 and 5) contained benign cellular components in variable amounts, but usually the amount of prostatic epithelium was increased. In this study, every secretion called "positive" for carcinoma cells contained clusters of malignant cells. In poorly differentiated carcinomas, single carcinoma cells were also plentiful. In the well differentiated carcinomas, the cells were not very typical and the presence of clusters of cells were considered essential for the diagnosis.

With variation depending somewhat on the degree of differentiation, the characteristics of the carcinoma cells, whether as single cells or clumps of cells, were: enlargement of the nuclei, crowding of the nuclei when the cells were in clusters (fig. 1), variation in the size of the nuclei (fig. 5 *A*), decrease in the relative amount of cytoplasm and indefiniteness of the cell border (fig. 5), hyperchromicity of the nuclei, prominent nucleoli (fig. 5 *B*) which were either dark or pale and mitotic figures (fig. 2), which were seen in about one third of the poorly differentiated carcinomas.

Confusing components of prostatic secretion were many, and the time spent in distinguishing them from malignant cells varied. The nuclei of squamous and transitional epithelial cells are large, and when the cytoplasm stains poorly these cells appear to have large nuclei and to lack cytoplasm. The nuclei may even contain pale nucleoli, but usually the similarity of these nuclei to those of other typically squamous cells and the lack of hyperchromicity were revealing.

*Results of Examination of Prostatic Secretion for Malignant Cells Compared with the Results of Microscopic Examination of Surgically Removed Prostatic Tissue in 41 Cases of Clinical Carcinoma of the Prostate*

| | Cases | |
|---|---|---|
| Secretion obtained | | 24 |
| Secretion positiv | 13 | |
| Secretion positiv , | 6 | |
| Secretion negative, tissue positive | 1 | |
| Secretion positive, tissue negative | 1 | |
| Secretion negative, tissue negative | 3 | |
| Secretion not obtained | | 17 |

A very confusing cell-like structure was found when spermatozoa were seen in the smears (fig. 4). These structures appeared to consist of hemogeneous dark blue nuclei with very eosinophilic cytoplasm. Even nucleoli were apparent at times. These cell-like structures were easily recognized most of the time, but gave considerable difficulty until experience was gained. They were seen in 14 of 100 cases of benign hypertrophy. Early in the study, 3 patients were tentatively considered to have carcinoma cells in the secretion, but they were all discovered to have benign lesions at transurethral resection. For further check, every piece (about 400) of tissue removed from these three glands, which weighed 27, 14 and 23 Gm. respectively, was sectioned by means of the frozen tissue technic, and no carcinoma was found. In an effort to locate the origin of these artefacts, smears were made from freshly removed seminal vesicles, epididymides and testicles. Nothing comparable was observed.

Confusing clumps of well differentiated prostatic epithelial cells were seen in the secretions of 4 patients who had clinically benign prostates. One of these 4 patients was later proved to have carcinoma of the most differentiated type (Broders'), and one rather definitely had a benign prostate, as indicated by the fact that every piece of 28 Gm. of tissue removed transurethrally, which the surgeon felt made up practically the whole gland, was checked with the aid of the frozen tissue technic and found to be benign. The other 2 of the 4 patients had to be considered as having benign prostates on the basis of the available evidence. The clumps of cells seen in the secretions from the malignant gland were no more, and perhaps even less, malignant appearing than those from the other 3. In the proved benign gland, sections showed some acini filled as a result of hyperplasia of the epithelium, an observation which offers a possible explanation for the clumps seen.

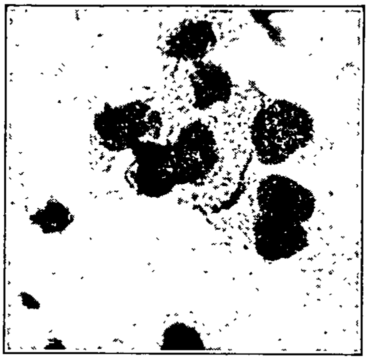

Fig. 4.—Secretion from a benign prostate showing the structures commonly seen, with spermatozoa. These structures may be confused with carcinoma cells (hematoxylin and eosin × 865).

Smears of expressed tissue were observed to be similar to smears of prostatic secretions from the same gland, except that in smears of tissue the prostatic epithelium predominated, leukocytes were few and nuclear detail was relatively poor. Figure 1 shows both benign and malignant cells in one of these smears, from a poorly differentiated carcinoma.

*Results of a Study of Secretions in 100 Cases of Clinically Benign Prostatic Hypertrophy.*—Of the 100 cases in which a diagnosis of benign hypertrophy was made preoperatively, carcinoma cells (fig. 3) were seen in the secretions of 3. The observations in these 3 cases were confirmed pathologically at transurethral resection. Similar histologic pictures were presented on examination of sections of tissue, the degree of malignancy being graded 2 (Broders' method). In these 3 cases symptoms, which were similar and referable to the urinary tract, included frequency, nocturia, urgency, smallness of stream, difficulty in starting the stream and some burning. The ages of these 3 patients fell in the fifth and sixth decades.

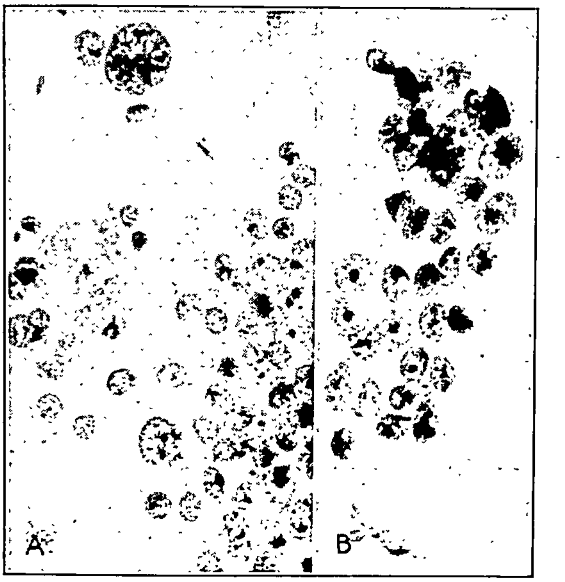

Fig. 5.—*A*, Prostatic secretion from a poorly differentiated carcinoma in which practically all cells seen are malignant, showing decided variation in size (hematoxylin and eosin ×430). *B*, carcinoma cells in secretion from a clinically malignant gland. Carcinoma was not found in removed tissue. Nucleoli may be noted (hematoxylin and eosin × 430).

In a fourth case in this series the prostate was found to be malignant (grade 1) on histologic examination. There were small glands that lacked papillary infolding; there was lack of stroma, and it was difficult to distinguish the cells from normal cells. However, the secretion from this patient was not considered diagnostic when it was compared with the secretion from benign prostates that showed, on section of tissue at surgical removal, hyperplasia of the epithelium and resultant filling of some of the acini.

*Results of a Study of Secretion in 41 Cases of Clinical Carcinoma of the Prostate* (table).—The cases in this series in which secretions were not obtained or in which no proof on examination of prostatic tissue was obtained were, clinically, all cases of advanced carcinoma of the prostate. Many of the patients had metastasis, and 5 of these from which secretions were not obtained had undergone resection previously.

The patient whose prostatic secretions failed to reveal carcinoma was observed, on examination of prostatic tissue, to have carcinoma of the most highly differentiated grade (grade 1).

In the 1 case in which prostatic secretions were positive for carcinoma cells (fig. 5 *B*) and the prostatic tissue did not show carcinoma, every piece of 19 Gm. of tissue removed at transurethral resection was sectioned and examined without carcinoma being found.

Of the cases in which both secretion and tissue were positive for carcinoma, in 2 the lesions were well differentiated carcinomas showing gland formation but malignant changes in the cells (grade 2), and in the rest the lesions were poorly differentiated carcinomas (grades 3 and 4). In 4 cases there was some question preoperatively as to whether the patient had a malignant lesion.

## COMMENT

The present study has demonstrated that carcinoma cells, the presence of which justifies the diagnosis of carcinoma of the prostate, can be found in prostatic secretions. There were many cases in which prostatic secretions were not obtained, and it seems worth while to point out that in all of these cases the lesion was unquestionably carcinoma of the prostate according to clinical evidence, 5 of the prostates having been previously resected. Since the usefulness of this test is directed at the cases of early questionable lesions and since these secretions were being studied only for the purpose of obtaining experience in recognizing malignant components, forceful attempts at obtaining secretions did not seem justified. There was no difficulty in obtaining secretions in the cases in which the presence of carcinoma was merely questioned or not suspected. Therefore, failure to obtain secretions is not expected to be an important issue in the effort to make an early diagnosis of cancer of the prostate. In an occasional case a second massage may be required before a satisfactory specimen is obtained.

The question of dissemination of carcinoma by massage of a malignant gland, which arises when this diagnostic procedure is used, cannot be answered. However, it is hard to conceive that massage would spread carcinoma more than does transurethral resection or aspiration biopsy, and there is no evidence in the literature that spread by those procedures occurs.

It appears from this study that the most differentiated grade of prostatic carcinoma, in which there are small glands that lack papillary infolding and cells that are difficult to distinguish from normal (grade 1), will not be detected with this test. Two such cases were encountered, and the lesion in neither could be called carcinomatous on the basis of evidence obtained from examination of the secretions. These probably comprise about 20 per cent of all prostatic carcinomas.[5] The prostatic carcinomas that were a little less differentiated, showing gland formation but presenting definite malignant changes in the cells (grade 2), were readily detected. The more poorly differentiated carcinomas (grades 3 and 4) were easily detected when only a few malignant cells were seen. The series of prostatic carcinomas studied is too small to allow conclusive statements as to the accuracy of this test, but it appears that about 80 per cent of these carcinomas should be detected when secretions are obtained. Except for grade 1 lesions, in this study there was good correlation between the observations on examination of secretion and the observations on examination of tissue. In the 1 exception carcinoma was not revealed in the tissue removed at transurethral resection, but the clinical picture was that of malignant disease and the secretion was so typical of carcinoma that a laboratory diagnosis of carcinoma was deemed justifiable.

An attempt was made, in several patients who required retention catheters, to obtain prostatic secretions at the time the catheter was removed for operation. As a rule these secretions were unsatisfactory, owing to the great amount of pus. Mulholland[16] had the same experience. This raises the question of whether severe prostatitis may mask carcinoma in respect to the study of secretions. The increased cellularity that results from the presence of pus makes the procedure more time consuming, but, in the present study, caused no error in diagnosis.

Little mention has been made of the study of the cytoplasm of the prostatic cells as an aid in the diagnosis of malignancy. It is felt from this study, in which the hematoxylin-eosin stain is used, that the diagnosis of carcinoma cells in prostatic secretions is primarily a nuclear diagnosis and also that squamous cells offer no help in the diagnosis. Several carcinoma cells, preferably in clusters, should be seen as the basis for the diagnosis; diagnosis based on the presence of single cells would be hazardous.

## SUMMARY

Clinical and laboratory investigations have been conducted to evaluate further the study of prostatic secretions as a routine diagnostic procedure. Studies were carried out on smears made by expressing pieces of prostatic tissue, on smears of prostatic secretions in a series of 100 cases of benign prostatic hypertrophy in all of which operation was performed and on smears in 24 of 41 cases of clinical carcinoma of the prostate in most of which histologic proof was available. All of these secretions were stained by means of a hematoxylin-eosin technic. In the course of the study, artefacts were observed which required further investigation.

## CONCLUSIONS

1. Carcinoma cells can be found in prostatic secretion, and finding them justifies the diagnosis of carcinoma of the prostate.

2. It appears that the most differentiated prostatic carcinomas, showing small glands that lack papillary infolding and consisting of cells which are difficult to distinguish from the normal (grade 1), will not be detected with this procedure. There appears to be good correlation between the results of the study of secretions and the results of the study of tissue sections in the detection of the other grades of prostatic carcinoma which show less differentiation.

3. Carcinoma cells were detected in 3 of 100 cases of clinical benign hypertrophy; therefore, such cells can be detected when carcinoma is not suspected clinically.

4. The presence of carcinoma cells and, in the case of the more differentiated carcinomas, the presence of clusters of carcinoma cells are essential for the diagnosis of prostatic carcinoma on the basis of examination of prostatic secretions.

5. Nuclei of squamous and transitional epithelial cells, clumps of benign prostatic epithelial cells and, especially, cell-like structures which appear in conjunction with spermatozoa may be confused with carcinoma cells until experience has been gained.

## ABSTRACT OF DISCUSSION

**Dr. Russell D. Herrold**, Chicago: The authors bring up the question of metastatic dissemination through manipulation in the collection of specimens for cytologic study. I agree that such dissemination is unlikely. In reviewing the successive roentgenograms of patients with carcinoma of the prostate seen between Jan. 1, 1941, and Jan. 1, 1948, my co-workers and I found that it was exceptional for demonstrable metastasis to occur in patients who did not have such evidence on the original examination. Our first observations with this method of diagnosis were concerned chiefly with nonsuspicious conditions in the higher age groups, in order to become more familiar with normal or abnormal cells associated with benign hyperplasia or inflammatory lesions. We found it helpful here to utilize the Wright stain. Also, in patients with proved carcionma clumps of cells like those of cancer were frequently seen and were later observed after the Papanicolaou stain. We are making further comparisons to determine whether smears examined after the Wright stain was used may serve as a useful screening process to rule out the necessity of the Papanicolaou method for lesions which on digital palpation impress one more as inflammatory than as malignant. I should like to emphasize the statement by the essayist that the identification of cancer cells is primarily a nuclear diagnosis based preferably on the observation of clusters of such cells. Since we have had comparatively few patients with lesions of the questionable type in which further confirmation could be made by postoperative histologic sections, we are not in a position at this time to comment on the exact value of preoperative cytologic study. However, the results of our examinations of secretions from patients with known lesions indicate that this method is an additional procedure of value to digital palpation, aspiration biopsy, roentgenologic study for metastasis and acid phosphatase determinations of the serum. Should this method become popular there will of course be many false negative reports, as with aspiration biopsy. This is not of too much concern, but false positive reports might have serious consequences. Therefore, observations from a single examination should be conservative until a great deal of experience with this method has been had. In the collection of prostatic secretions we prefer to obtain the whole amount in a container; then, after thorough shaking, the spreads are made, thus assuring a fraction of the whole. If insufficient secretion is obtained the patient is instructed to void about ½ ounce (14 Gm.) in a wide mouth 1 ounce bottle, and this is centrifuged and smears made of the sediment. If centrifugation cannot be done promptly, the specimen should be kept in the refrigerator.

**Dr. Donald Albers**, Rochester, Minn.: Dr. Herrold asked about the lapse of time after one of these slides is fixed before it can be stained adequately. I do not know the maximum that will still allow one to get good distinction in the cells. I know that some of the slides we have fixed for thirty minutes have been in the dry state for two or three days without deteriorating to any particular degree. I emphasize that it is important that one leave them in the fixative for thirty minutes. In the laboratory when these slides are to be held over and stained later they are usually just left in the fixative.

# DIAGNOSTIC SIGNIFICANCE OF FAILING VISION

LAWRENCE T. POST, M.D.
St. Louis

In this paper my real purpose is not to be instructive medically, in the sense of trying to convey the ophthalmologic pictures of numerous ocular diseases. I do hope, by outlining some of the close interrelations of general medicine and ophthalmology in one subdivision of the latter specialty, to combat in a small way the tendency toward the isolation of ophthalmologic from general medical practice.

I believe that both ophthalmologists and optometrists have useful and legitimate places in eye care, but I am strongly opposed to the efforts of many optometrists to become the ophthalmic consultants for the medical profession and to eliminate the ophthalmologist from the picture of ocular care except for surgical and local treatment of eye disease. This can result only in general practitioners', in all but the great population centers, having to take over the surgical and other treatment of the eye, a course that will be detrimental to medical welfare and is surely not desired by such practitioners. Furthermore, I do not believe that the optometrist with his limited medical background can serve satisfactorily as a medical consultant.

The oculist's practice may be divided into four main subdivisions: diagnosis, surgical treatment, local treatment and refraction. It is in the first named that general medicine and ophthalmology are most closely linked. It is possible to discuss, and only briefly, a few of the many diseases that have both general medical and ophthalmologic pathologic aspects, and no attempt is made in this paper at a comprehensive study.

In order to approach the subject in a somewhat logical manner, causes of failing vision are discussed as they affect the cornea, iris, ciliary body and choroid; retina, optic nerve, lens and vitreous, and, finally, failure from disuse.

### CORNEAL CAUSES OF VISUAL FAILURE

Considering corneal causes of visual failure, tuberculosis is no rarity. It is usually considered an allergic manifestation. The treatment of choice in addition to rather ineffective local medication is the general treatment of tuberculosis; it is the family practitioner who knows most about the patient's particular situation and is best able to give advice to him and to insist that it be carried out.

Corneal degeneration is not infrequent in old persons. The central areas, anteroposteriorly, may become less transparent. Not rarely nodules appear in the posterior glass membrane that look like tiny raindrops on the rear surface of the cornea when seen with the corneal microscope. Epithelial degeneration also occurs, and for none of these diseases does the ophthalmologist have a cure. Corneal transplantation, which seems so logical, is not ideal, because it is often followed by a degeneration of the graft similar to that in the section removed.

Ulcers are another important cause of visual failure, and they occur throughout life, their causes varying from gonorrhea in infancy through phlyctenular keratitis in youth to malnutrition of age. In preadolescence

Read before the Section on General Practice at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 24, 1948.

there is the interstitial keratitis of syphilis, indicating the general treatment for syphilis and the local use of atropine and dark glasses.

### DISEASES OF IRIS, CILIARY BODY AND CHOROID

Concerning diseases of the iris, ciliary body and choroid, allergic reactions are seen as frequently in ophthalmologic practice as in every other department of medicine. They occur chiefly in the eye in the form of conjunctivitis and lid reactions, the former the so-called vernal conjunctivitis, and as such they are seldom responsible for failing sight. But in scleritis and uveitis they are important causes for gradual loss of vision.

In tuberculosis the lesion in the uveal tract, that is, iris, ciliary body and choroid, may originally have been the seat of the organisms derived from other foci; against this idea it must be mentioned that bacilli are seldom seen in sections of these eyes, though it is also true that such eyes as are removed have been long subject to the disease and tissue reaction may have destroyed the organisms.

The most dreaded form of uveitis is sympathetic ophthalmia, which is probably due to sensitivity to uveal pigment. The oculist almost never has the materials for making allergic tests and must, therefore, refer patients with these diseases to the medical practitioner both for help in finding the offending allergen and for desensitization if possible. The future would seem to hold some possibilities for nonspecific desensitization, and for leadership in the search for this the ophthalmologist looks to the medical investigator. Differential diagnosis of allergic uveitis depends on tests for allergy and the elimination of other more easily identifiable inflammations, such as leprosy, syphilis and sympathetic diseases; syphilis is suggested by a positive serologic reaction and sympathetic disease by a history of injury.

### RETINAL CAUSES OF DIMINISHED VISION

Retinal causes of diminished vision are numerous. Diabetes affects the eye late in the course of the disease, particularly in the form of chorioretinitis, though undoubtedly some cataracts have this as their cause. Diabetes, therefore, may be the cause of gradual loss of sight, and, though the onset is late, once it has started it is implacable; its presence is to be suspected in gradual visual failure in the middle years. There is no pain, and there are no external manifestations. Often the first ocular symptom is visual failure, and when this occurs the chorioretinitis is usually so severe that it is beyond curing. It may take place in fairly well treated patients, and, unfortunately, the usual therapy for diabetes is completely ineffective with respect to retinal lesions.

In cardiovascular-renal disease is found perhaps the closest bond between general medical practitioners and ophthalmologists. In these conditions one looks for both sudden and gradual visual loss, the former especially associated with large retinal hemorrhages and the latter with arteriosclerosis and small hemorrhages and exudates. Probably the eyegrounds show the changes of malignant hypertension as early as they are to be noted anywhere in the body. Obviously, the treatment rests with the physician, and the ophthalmologist's part is only that of observation and of keeping the internist informed of the retinal condition in order to protect as well as possible the vision of the patient.

Degenerative changes that so frequently accompany old age need special consideration. It is fortunate that the study of geriatrics is assuming increasing importance. To combat the gradual visual loss associated with retinal degenerations, one must combat old age itself. The retina suffers in this condition primarily from malnutrition and probably an accumulation of waste products. The struggle against old age demands sedulous perseverance. As old age attacks, it seeks every weakness in the patient's defensive armor, and it is the physician's duty to find and fill these chinks before the enemy penetrates too far. For the retina everything that will help circulation and metabolism is worth while, such as infra-red radiation, long-acting vasodilators and vitamins for vitamin deficiencies. For example, most old persons need more thiamine chloride than they normally get. They may also need aids to elimination. The oxidation of the tissues should be accelerated. For helping the old, who through degenerations are fast losing vision, their most prized possession, the ophthalmologist turns to his medical confrere.

### OPTIC ATROPHY

Optic atrophy is a major reason for failing sight. Among its most important medical causes are syphilis, hypophyseal tumor and multiple sclerosis. In all of these diseases the ophthalmologist is often the first to make the diagnosis, but his part in the developing picture thereafter is largely advisory from the visual point of view, and he depends on the general medical practitioner, or in some cases the surgeon, for the treatment. In about 80 per cent of supratentorial neoplasms one expects to find choked disks, whereas in hypophyseal tumors atrophy of the papillomacular bundle is the rule. In multiple sclerosis the onset may be associated with an optic neuritis, but oftener one sees the later picture of temporal pallor of the nerve head with loss of central vision.

Failure of sight from optic atrophy may be sudden, as from toxemias from drugs, such as quinine or methyl alcohol, or gradual as from injudicious use of some arsenicals, such as tryparsamide.[8] In the administration of the last named drug no precaution is as important as mapping visual fields frequently. Diminution of these is a positive indication for discontinuance of the drug.

How much can be accomplished toward aiding vision in optic atrophy from syphilis? The results in my own patients by any form of treatment have not been encouraging; those by induced malarial infection have seemed best, but a poor best.

### PERIPHERAL FIELD CHANGES

Peripheral field changes occasionally bring the patient to the eye physician, but it is surprising how far these may progress before attracting the patient's attention, as in the case of chronic simple glaucoma, the most frequent cause of blindness of middle and old age. This subtle disease creeps in without causing pain or redness of the eyes and is noticeable only to a discerning patient before it is too late by a diminution in the visual field or halos about lights. Glaucoma is probably associated with some hidden systemic disease. The only thing that the general practitioner as yet can do to aid in the fight against this disease is to help in its early discovery by using his ophthalmoscope intelligently and by urging his patients to consult their ophthalmologists regularly through the dangerous years, even as the ophthalmologists should urge periodic examination for the determination of the medical status of their patients.

### CATARACT

Senile cataract is another important factor in visual failure. Undoubtedly a nutritional basis will be found for cataracts, as many have suggested, and medical research may bring this to light. It is already known, for example, that such drugs as naphthalin and dinitrophenol can produce them and that hypoparathyroidism may be a cause.

With the modern intracapsular method of extraction, an immature cataract can be as easily removed as a mature one. Patients are best pleased with the result when operation is delayed until ordinary print can no longer be read with the better eye. Rarely in cases other than those in which industrial safety or overripening of the cataract demand earlier operation should this be done, because the patient is disappointed if he finds postoperatively that the eye which was not operated on is still the more useful, and, truly, the best eye, minus its crystalline lens, is a poor substitute for the normal. Good results should be obtained by operation in from 90 to 95 per cent of cases. Fusion usually follows a good surgical outcome when both eyes are operated on, and the double operation—each eye on a different date—is advocated unless extreme age or other urgent reason indicate otherwise.

### DISUSE

Greatly diminished vision from lack of use of an eye occurs in infancy and childhood and, if not treated promptly, is incurable, but if intelligently handled it can almost always be materially helped. The family physician should insist that such a child be referred immediately to an oculist. Temporizing is always costly and often disastrous.

### COMMENT

I suggest that the ophthalmologist be used as a true consultant for all that he may be able to offer diagnostically and not just to determine visual fields or for an opinion as to whether a disk is choked or not, even as the ophthalmologist should not ask the general practitioner for an opinion on a patient's blood pressure only or for some specific test, but rather should ask for a full medical opinion of the nature of the case. In such a mutual consultative relationship will the best interest of the patient be served. The ophthalmologist needs the general practitioner and, in turn, can be of help to him.

## ABSTRACT OF DISCUSSION

Dr. Paul O. Hagemann, St. Louis: A diversity of medical conditions may affect vision. Patients suffering from degenerative disease may have visual difficulty and lesions of the cornea and the retina. In those with nutritional deficiency corneal lesions and lesions of the lens may develop. In those with metabolic disturbances retinal lesions, such as diabetic retinopathy, may develop, and in patients with tetany lenticular opacity may develop. When using certain drugs, one is obligated to keep in mind possible eye complications due to hypersensitivity, such as lenticular opacities and optic atrophy. Those who have been studying the treatment of syphilis feel that tryparsamide no longer has a place in the treatment of neurosyphilis in view of the excellent results being obtained with penicillin. In regard to patients with vascular disease, much can be learned about the state of the vascular system by the observation of the vessels in the fundus. For patients being considered for sympathectomy, valuable prognostic information can be given by the ophthalmologist. Not infrequently the differential diagnosis between malignant hypertension and cerebral neoplasm is difficult. Here, again, the ophthalmologist can help in this differentiation. In a recent survey of blindness due to infection, it was pointed out that general or systemic infections are four times as prevalent a cause of blindness as is local infection of the eye. Tuberculosis can be such a cause, with involvement of the cornea, uvea or retina; syphilis may be, with involvement of the cornea, uvea or optic nerve, and foci of infections are regarded as a common cause of this type of disorder. The obligation of the general practitioner, then, is to survey the patient for such foci—common ones, such as infected teeth, tonsils and sinuses. Not infrequently one sees eye manifestations in rheumatic fever and in rheumatoid arthritis. Principally this is in the form of a uveitis. This subject has been investigated to some extent, and it is felt that there are certain reasons that these conditions occur in the same disease process. There are great anatomic similarities between the ciliary processes of the eye and the synovial villi in joints. It is also of interest that in experiments with animals the incidence of arthritis as well as uveitis occurs in a far higher percentage of hyperimmune animals, emphasizing the allergic aspects of this subject. There is a reciprocal obligation between the ophthalmologist and the general practitioner. The ophthalmologist can help by classifying the disorders as they occur in the eye and also can supervise the local management.

## EXTREME HYPERTENSION IN A CHILD CURED BY NEPHRECTOMY

### Report of a Case and Review of the Literature

BENJAMIN M. GASUL, M.D.
JULIUS M. GLASSER, M.D.
and
AARON GROSSMAN, M.D.
Chicago

M. C., a girl aged 9, was first seen on Nov. 10, 1946, with a history of having awakened early in the morning complaining of generalized abdominal pain, followed by repeated attacks of vomiting. She had had three attacks of vomiting and generalized abdominal pain during the previous three months, each of which lasted about twenty-four hours and then cleared up completely. In addition, the mother stated that the child had complained of occasional headache and had nocturia and enuresis during the past two years.

Physical examination revealed a well developed, restless child, complaining of generalized abdominal pain. Temperature was 99.4 F., pulse rate 130 and regular and respirations 30 per minute. The abdomen was soft and there were no palpable masses, rigidity or tenderness. The blood pressure varied from 160 systolic and 130 diastolic to 175 systolic and 125 diastolic. Blood pressure in the right leg was 190 systolic and 152 diastolic and in the left leg 188 systolic and 140 diastolic. No abnormalities were observed on examination of the heart. Ophthalmoscopic examination revealed numerous hemorrhages on the disk and scattered throughout both fundi. There were many grayish white exudates in both macular regions.

The laboratory tests showed clear urine, specific gravity 1.010, albumin 1 plus and no red or white blood cells. The blood cell count showed 4,210,000 erythrocytes, hemoglobin 85 per cent Sahli (14.4 Gm.) and leukocytes 9,300, with 77 per cent polymorphonuclear cells, 20 lymphocytes and 3 monocytes. The roentgenogram of the heart and the electrocardiogram revealed no abnormalities.

The normal abdominal observations, the normal temperature and the blood cell count definitely excluded acute appendicitis;

---

From the Pediatric and Urologic Services of Mt. Sinai Hospital, Chicago.

the high blood pressure in the upper extremities, the still higher pressure in the lower extremities and the normal cardiac observations excluded coarctation of the aorta. The history, the hypertension and the gastrointestinal observations pointed strongly to chronic nephritis and possibly impending uremia. An emergency test of the chemical content of the blood was then ordered and performed on the day of admission. It showed normal observations: urea nitrogen 13.6 mg., sugar 133 mg., chlorides 580 mg., calcium 10.8 mg. and carbon dioxide combining power 66 volumes per cent.

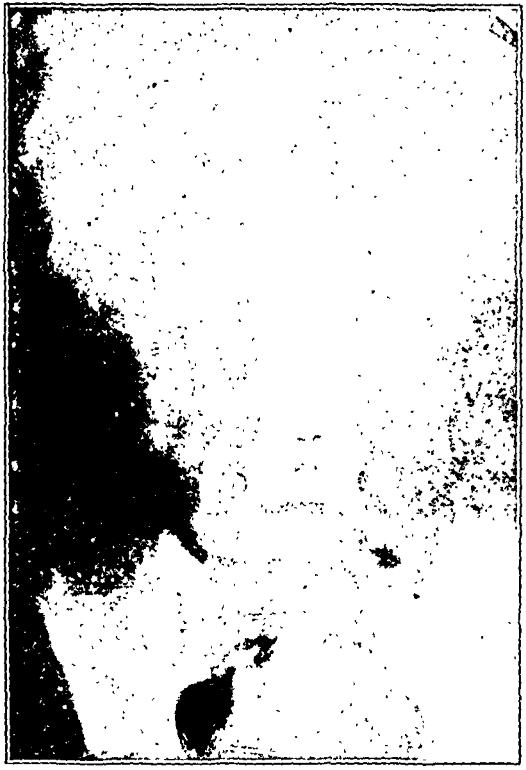

Fig. 1.—Intravenous pyelogram shows an enlarged but normal left kidney. On the right, the renal shadow cannot be visualized.

On the next morning, November 11, the child complained of a severe headache, and an ophthalmologist, Dr. Carl Apple, was called in. His observations were as follows: Both disks were edematous; the margins were obscured by edema, and both were moderately elevated, about 1½ to 2 diopters. Glistening stellate exudates were seen in both maculas, and between the right macula and disk were numerous dirty gray exudates. The retinal vessels crossed over these exudates uninterruptedly; a few of the exudates covered the retinal vessels. There were also numerous small rounded and flame-shaped hemorrhages, especially pronounced below the right disk and some in the periphery of the right fundus as well as between right disk and macula. In the left fundus, the exudates and hemorrhages were less pronounced. The retinal vessels in both fundi showed an auriculoventricular ratio of 1 to 3. Some of the smallest vessels were obscured by the retinal edema. The hemorrhages as well as the exudates were in the outer layer of the retina.

On the same day, the child had several generalized convulsions of several minutes' duration and the blood pressure rose to 200 systolic and 140 diastolic. A spinal puncture revealed a uniformly bloody fluid (nontraumatic). The fluid did not clot, sugar was 67 mg. per hundred cubic centimeters (with blood sugar of 121 mg.), and culture and smear as well as the reactions to the Wassermann and colloidal gold curve tests were negative.

Because of the normal observations of the urine and chemical content of the blood, a "Goldblatt" kidney or a pheochromocytoma was seriously considered.. We believed that an intravenous pyelogram was definitely indicated, because this was the only way in which the site of the involved kidney could be localized. Although the condition of the patient appeared desperate—in addition to the extreme hypertension, a cerebral hemorrhage developed and the blood pressure rose to 214 systolic and 164 diastolic—an intravenous pyelogram was performed, and Dr. Arendt reported as follows: Intravenous pyelogram (fig. 1) showed incomplete filling of the pelvis on the left side; however, the calyces appeared to be normal, without any dilatation or clubbing. The left renal shadow was considerably enlarged, but normal in contour. On the right, the renal shadow could not be visualized. There was a faint shadow suggesting a considerably contracted renal shadow. On the thirty minute roentgenogram there was a suggestion of a slight amount of contrast medium in the upper calyx of the right kidney. These observations indicated the presence of a hypoplastic or contracted right kidney, which was practically functionless, associated with an enlarged apparently normal functioning left kidney.

The diagnosis was unilateral involvement of the right kidney and an apparently normal left kidney. Cystoscopic examination showed the bladder to be essentially normal. The left ureteral orifice was identified and found to be normal. The right ureteral orifice was difficult to identify. Intravenously administered indigo-carmine appeared in good concentration from the left kidney in five minutes, but no dye was seen coming from the right ureteral orifice.

On November 15, the right kidney was explored. The whole kidney appeared diseased, and a right nephrectomy was done. The postoperative course was uneventful. Within twenty-four hours after the operation, blood pressure dropped to 160 systolic and 120 diastolic and within ten days had dropped to 128 systolic and 90 diastolic.

The pathologic report of the right kidney (Dr. I. Davidsohn) was as follows: The kidney, with a ureter of 6 cm. in length, weighed about 17 Gm. (fig. 2). The organ measured 5 by 2 by 1.2 cm. The capsule was stripped with some difficulty. The surface was grayish red and somewhat granular. The section surface revealed the parenchyma to be reduced, measuring between 4 and 6 mm. The cortex was rather thin, measuring about 1 mm., and throughout the parenchyma the walls of the blood vessels were outstanding and thickened. The pelvic fat tissue was increased. The pelvis itself was enlarged and dilated, as were the calyces. The mucosa was edematous and showed a few hemorrhages. The ureter was not dilated. The wall of the renal artery was gaping. There was an accessory artery near the upper pole, the lumen of which was also gaping.

Microscopic examination (fig. 3) revealed complete hyalinization of the glomeruli; the interstitial tissue was increased and heavily infiltrated with round cells. Only in a few places some islets consisting of tubules could be found. A large section contained only one glomerulus. The pelvic mucosa was thickened and heavily infiltrated with round cells which formed some follicles. Medium-sized and small arteries showed decided thickening of their walls. The diagnosis was pyelonephritic atrophy of the right kidney.

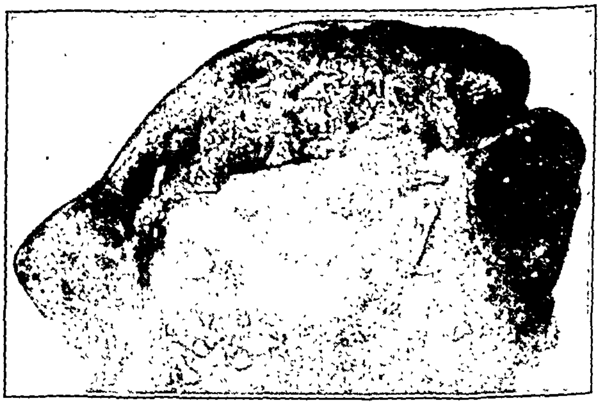

Fig. 2.—Close-up view, with pyelonephritic atrophy and petechial hemorrhages in the pelvis.

The patient was discharged from the hospital on the eleventh postoperative day, with a blood pressure of 134 systolic and 90 diastolic and normal urine and chemical content of the blood. The child was examined a number of times since then and when last seen, on Nov. 8, 1948, two years after the nephrectomy, the blood pressure was 125 systolic and 80 diastolic, the urine was normal and the blood contained 18 mg. urea nitrogen, 2.6 mg. uric acid and 0.8 mg. creatinine per hundred cubic centimeters. The report of the ophthalmologist, Dr. Carl Apple, on September 13 was: Right vision (unaided) was 1.0; left vision (unaided) was 0.4 — 2. With glasses right vision was normal and left vision was normal. The left eye converged 5 degrees. Fundoscopic examination showed normal appearance of the fundi. In the right macula there were several small dark pigment spots; in the left macula, there were about fifteen similar spots. There were no hemorrhages or exudates. The retinal vessels had a normal appearance.

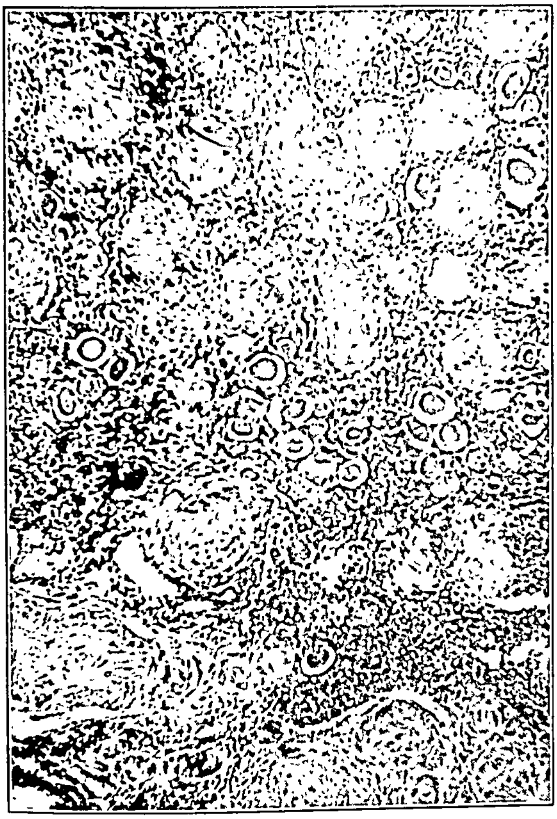

Fig. 3.—Chronic pyelonephritis. Hyalinized glomeruli with atrophic tubules and inspissated casts.

COMMENT

The experimental work of Goldblatt and his co-workers[1] precipitated great interest in the relationship between hypertension and certain types of unilateral disease of the kidney. Their work, confirmed by other investigators, consisted in the use of an adjustable silver clamp which permitted the degree of constriction of the renal vessels to be increased at will, thereby producing renal ischemia. With constriction of one renal artery there was a rise in the blood pressure for a variable length of time. With bilateral constriction of the renal arteries hypertension was maintained indefinitely. Later Goldblatt found that excision of an ischemic kidney at the height of hypertension following unilateral constriction of the renal artery resulted in a prompt return of the blood pressure to normal. No satisfactory evidence has been adduced that the nervous mechanism plays a part in the production of experimental hypertension.[2] The exact mechanism involved in the production of such hypertension is unknown, but it is believed that the ischemic kidney releases a pressor substance known as renin. This substance has been prepared and purified.[3] Renin is not in itself a pressor substance, but it reacts with a pseudoglobulin renin activator (hypertensinogen) to form a highly active substance named angiotonin (hypertensin). Angiotonin, when injected intravenously produced a sharp immediate rise in arterial pressure. It is believed by some investigators that the normal kidney either destroys the pressor substance or secretes an antipressor hormone.[4]

Numerous clinical reports have appeared in the literature with some conflicting opinions as to the merits of nephrectomy in unilateral renal disease. However, a thorough review of the literature reveals only 22 cases of hypertension in adults in which blood pressure has remained normal one or more years following operation.[5] In children, only 9 cases could be found in which the blood pressure had remained at normal level for at least one year following the operation; in 8, unilateral pyelonephritis was the cause of the hypertension, and in 1 an ectopic kidney with a smooth muscle plug in the renal artery was responsible for the hypertension (table).

In our case, atrophic unilateral pyelonephritis was the cause of the hypertension, and the successful result demonstrates that every case of hypertension in a child should be carefully studied; if a unilateral kidney involvement is found with the other kidney normal or showing compensatory hypertrophy, an immediate nephrectomy should be performed.

SUMMARY

Nephrectomy was performed in a child, 9 years of age, with extreme hypertension due to unilateral atrophic pyelonephritis. The blood pressure, the urine and the chemical content of the blood had remained normal for twenty-four months following the operation. The pronounced hemorrhagic retinitis noted before the operation was no longer present at the time of last examination.

JOSÉ F. MALONADO, Ph.D.
San Juan, Puerto Rico

The preliminary results obtained with the administration of hetrazan® (1-diethylcarbamyl-4-methylpiperazine hydrochloride) to 26 persons with circulating microfilariae of Wuchereria bancrofti have already been published.[1] Although the dose and length of treatment were varied, as this was the first experience with this drug in human beings, the microfilariae in all instances rapidly disappeared from the blood stream, and in 13 of the 26 patients the smears were consistently negative from eight to eighty-three days after one course of treatment. In 4 of the cases there was clinical evidence of death of the adult worm. Little or no toxic effects following administration of the drug were encountered.

*Number of Microfilariae in Nocturnal Blood from Patients Treated with "Hetrazan"*

Monthly follow-up examinations of the nocturnal blood of these patients have been performed during a period of fifteen months. At the end of this period the patients were given a physical examination with particular emphasis on the state of the lymphatic system and were questioned intensively regarding symptoms known to be associated with clinical filariasis.

The table records the results of the microfilarial counts performed from the third to the fifteenth month after treatment. Of the 26 original patients, 23 could be examined at the end of the fifteen month period. One patient (case 24) was lost track of when he moved to the United States. Two other patients (cases 2 and 9), who had shown persistently negative microfilarial counts for many months, failed to return for checkup after the thirteenth and the fourteenth month, respectively.

Thirteen of the 23 patients examined (56.5 per cent) showed negative microfilarial counts at the end of the fifteen month period. Also, these patients either had no microfilariae or an insignificant number of them at the time of the monthly examination. The remaining 10 had very low counts, in all cases considerably lower than the original values before treatment. The patients who had received the highest total dose of the drug were the ones showing persistently negative counts in all examinations, while those who received the lower total dosage were the ones presenting positive smears, though invariably with extremely low values. Presumably, and in the light of further experiences with this drug, this latter group received insufficient dosage. Even so, these insufficiently treated patients, who presented low counts three months after treatment, have shown no tendency to relapse, as their counts have persisted at low levels throughout the entire period of observation.

Twenty-two of the 23 patients remained free of symptoms referable to the lymphatic system which might be attributed to filariasis. One patient (case 7), seven months after treatment, had pain over the anterior aspect of the upper third of the left thigh and a tender nodular swelling at the femoral region. There was no fever, no redness of the overlying skin, no lymphangitis and no enlargement of the inguinal nodes. This swelling disappeared entirely within a week. Final checkup at the end of the fifteen months revealed no abnormalities. The 4 patients who had had nodular swellings early during treatment showed no evidence of residual disease of their lymphatic system when last examined.

### SUMMARY

*Thirteen (56.5 per cent) of 23 persons with microfilariae of* Wuchereria bancrofti *were found free of the infection as* evidenced by negative microfilarial counts performed fifteen

---

From the Departments of Medical Zoology and Clinical Medicine of the School of Tropical Medicine, San Juan, Puerto Rico.

These studies were carried out with the financial aid of the Lederle Laboratories Division, American Cyanamid Company, Pearl River, N. Y.

[1] [illegible] and Hewitt, R.: Treat- [illegible] -Piperazine [illegible] ) 1947.

months after treatment with hetrazan® (1-diethylcarbamyl-4-methylpiperazine hydrochloride). The remaining 10 had very low counts, which had persistently remained at low levels since the end of the course of treatment. There was no increase in the number of microfilariae during the follow-up period in any of the patients which might suggest a relapse.

In general, the patients who received the highest total doses were the ones with negative smears at the end of the fifteen month period. The others probably did not receive sufficient amount of the drug to eradicate the infection entirely. All but one of the group of 23 patients remained symptom free. None of the patients showed evidence of disease in their lymphatic or other systems suggesting clinical filiariasis.

These observations would seem to indicate that hetrazan,® when given in adequate dosage to patients infected with W. bancrofti, cleared the blood stream of microfilariae for periods of at least fifteen months. There was no clinical evidence of residual lymphatic disease which might be attributed to the filaricidal action of the drug.

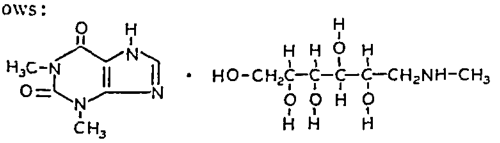
## NEW AND NONOFFICIAL REMEDIES

*The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.*

Austin Smith, M.D., *Secretary.*

**THEOPHYLLINE-METHYLGLUCAMINE.—Glucophylline—Abbott.**—An equimolecular mixture of theophylline-U. S. P. ($C_7H_8N_4O_2.H_2O$) and methylglucamine ($C_7H_{17}NO_6$). Dosage forms of theophylline-methylglucamine contain not less than 95 per cent nor more than 105 per cent of the labeled quantities of theophylline and methylglucamine. The structural formula of theophylline-methylglucamine may be represented as follows:



*Actions and Uses.*—Theophylline-methylglucamine is identical in action and therapeutic purpose with aminophylline (theophylline ethylenediamine) U. S. P. over which it has no advantage. It is therefore similarly useful orally and by injection to produce the effects of theophylline when a more soluble salt than theophylline and sodium acetate is needed. It is employed orally as a diuretic and myocardial stimulant for pulmonary edema and paroxysmal dyspnea in conjective heart failure, and for the relief of Cheyne-Stokes respiration. It is also useful in the relief of acute bronchial asthma, particularly in patients who have become unresponsive to epinephrine. As with aminophylline, claims for its use in coronary or peripheral vascular disease and in hypertension are not recognized on the basis of available evidence.

*Dosage.*—Theophylline-methylglucamine represents about 50 per cent of theophylline, as compared to about 78 per cent contained in aminophylline U. S. P., so that the ratio of dosage to the latter is approximately 2 : 3. On this basis the dosage recommended for theophylline-methylglucamine should be about one and one-half times the dose ordinarily prescribed for aminophylline.

Orally, from 0.15 to 0.75 Gm. three or four times daily after meals, given continuously for only a few days at a time with intervening rest periods of one or two days. Intramuscularly, 0.75 Gm. in 2 cc.; intravenously 0.36 to 0.75 Gm. in 10 cc. to 20 cc. As with aminophylline, intravenous injection should be made slowly to avoid untoward effects.

*Tests and Standards.*—

Transfer a portion of powdered tablets or of solution, equivalent to approximately 0.35 Gm. of [illegible] a separatory funnel. Add 25 cc. of wa[illegible] T. S., and titrate to a faint red color [illegible] acid. Each cubic centimeter of tenth-normal hydrochloric acid is equivalent to 19.52 mg. of methylglucamine. The amount of methylglucamine found is not less than 95 per cent and not more than 105 per cent of the labeled amount of methylglucamine.

To the mixture that has been titrated in the separatory funnel add 4 drops of tenth-normal hydrochloric acid and extract with four portions of 25 cc., 20 cc., 15 cc. and 15 cc. of a mixture of three volumes of chloroform and one volume of isopropyl alcohol. Filter the extract through a small dry filter paper into a dried and tared evaporating dish. Wash the filter with a small amount of the extraction solvent and evaporate the combined extract and washings on a water bath. Dry the residue to constant weight at 100 C.: the weight of the residue, multiplied by 1.100, is equivalent to not less than 95 per cent nor more than 105 per cent of the labeled amount of theophylline U. S. P.

The theophylline employed in [illegible] preparations meets the requirements of t[illegible]

METHYLGLUCAMINE ($C_7H_1$[illegible] white to yellowish-white, odorless crystals which melt from 128 to 131 C. It is freely soluble in water, slightly soluble in alcohol, and practically insoluble in chloroform and in ether.

To 5 cc. of 5 per cent methylglucamine solution add 5 cc. of alkaline cupric tartrate T. S. and heat to boiling: no reduction of copper occurs *(absence of reducing substances).*

Dry about 1 Gm. of methylglucamine to constant weight at 100 C.: the loss in weight is not more than 0.1 per cent.

The specific rotation, [α]25/D, of a 10 per cent solution of methylglucamine in water is approximately — 16.3 degrees.

Ignite about 1 Gm. of methylglucamine, accurately weighed: the ash is negligible.

Dissolve 1 Gm. of methylglucamine in 25 cc. of water: the heavy metals limit (*U. S. P. XIII,* p. 657) is 20 parts per million.

The nitrogen content of methylglucamine when determined by the Dumas method is not less than 7.0 per cent or more than 7.2 per cent.

Transfer about 0.4 Gm. of methylglucamine, accurately weighed, to an Erlenmeyer flask and add 25 cc. of water and 2 drops of methyl red T. S. Titrate the mixture with tenth-normal hydrochloric acid. Each cubic centimeter of tenth-normal hydrochloric acid is equivalent to 19.52 mg. of methylglucamine. The amount of methylglucamine found is not less than 98 per cent, calculated to the dry substance.

Abbott Laboratories, North Chicago, Ill.

**Solution Glucophylline:** 0.366 Gm. in 10 cc. ampuls.

**Solution Glucophylline:** 0.732 Gm. in 2 cc. and 20 cc. ampuls.

**Enterab Tablets Glucophylline:** 0.152 Gm. Each tablet is enteric coated with a resin prepared from stearic acid, phthalic anhydride and glycerine.

**Tablets Glucophylline:** 0.152 Gm. and 0.304 Gm.

U. S. patent 2,161,114 (June 6, 1939; expires 1956).

Zemmer Co., Inc., Pittsburgh 13

**Tablets Aminophylline:** 0.1 Gm. and 0.2 Gm.

**Enteric Coated Tablets Aminophylline:** 0.1 Gm. and 0.2 Gm. Each tablet is enteric coated with a mixture of keratin and shellac.

**DICUMAROL** (See New and Nonofficial Remedies 1948, p. 351).

The following dosage form has been accepted:

Schieffelin & Company, New York 3

**Tablets Dicumarol:** 100 mg.

Licensed by the Wisconsin Alumni Research Foundation.

**DIGITOXIN-U. S. P.** (See New and Nonofficial Remedies 1948, p. 267).

The following dosage form has been accepted:

Abbott Laboratories, North Chicago, Ill.

**Solution Digitoxin:** 0.2 mg. per cc., 1 cc. ampuls.

**Tablets Digitoxin:** 0.1 mg. and 0.2 mg.

**SODIUM ASCORBATE INJECTION-U. S. P.** (See New and Nonofficial Remedies 1948, p. 561).

The following dosage form has been accepted:

Kremers-Urban Company, Milwaukee 1

**Solution Sodium Ascorbate:** 100 mg. per cc., 2 cc. ampuls.

**ASCORBIC ACID-U. S. P.** (See New and Nonofficial Remedies 1948, p. 559).

The following dosage form has been accepted:

Kremers-Urban Company, Milwaukee 1

**Tablets Ascorbic Acid:** 1[illegible]0 mg.

been undertaken by numerous investigators. Hess[5] and his associates of Georgetown Medical School not only made accurate assays of the amino acid content of various egg proteins but a parallel determination of their growth-promoting properties. Whole egg, whole white and whole yolk proteins were defatted and dehydrated by repeated treatments with acetone, alcohol and ether. The final products were analyzed for nitrogen, sulfur, cystine, cysteine, methionine, phenylalanine, tryptophane, threonine, methionine, histidine, lysine and arginine. The only essential amino acids not assayed were leucine, isoleucine and valine, which are present in such large amounts in eggs[6] that it is difficult to imagine an inadequate amount of these amino acids in any of their preparations.

Groups of 8 or 9 weanling rats were each fed 10 per cent of one of these proteins added to 90 per cent of their routine nonprotein mixture. By the end of two weeks the average gain in weight was calculated for each group of rats. This gain divided by the average total protein intake for the two week period gave the protein efficiency ratio for the selected protein.

Thus in one group of rats fed 10 per cent commercial egg white the average initial weight was 49.8 Gm. per rat. This increased to an average of 104.1 Gm. by the end of two weeks, an increase of 54.4 Gm. The average total food intake for the two week period was 161.1 Gm., containing 16.1 Gm. of protein; 54 divided by 16.1 equals 3.37, the protein efficiency ratio for this protein. Thus determined, the ratio was found to vary from 3.51 to as low as 2.33 for the seven protein preparations tested.

The most important comparison was between two samples of whole egg proteins prepared by different technicians. Tested on groups of rats, sample A gave a protein efficiency ratio of 3.12, while sample B gave only a 2.33 ratio. Thus, sample A was 50 per cent superior to sample B in nutritive value. Analyses showed that within the limits of the experimental error the two samples were identical in amino acid content, except for the one amino acid, cysteine. This was present in normal amounts in sample A, but absent from sample B. Addition of 0.25 per cent cystine to sample B raised its nutritive value from 2.33 to 2.38. Here we have two protein samples, sample A (3.12) and cysteinized sample B (2.38), containing identical amounts of all known essential amino acids. Nevertheless, sample A has a nutritive value 50 per cent higher than cysteinized sample B.

From this Hess concluded that in addition to the amino acids, other factors play a role in the nutritive value of proteins. Whether or not these unknown egg protein factors are identical with Zucker's[7] "zoophein" or with the "animal protein factor" of Bird[8] has not been determined. Casein is known to contain "zoopherin," from which it can be extracted with alcohol.[9] The Bird "animal protein factor" is an essential factor in poultry nutrition, and is found in particularly high concentration in cow manure.

# Current Comment

## COMMITTEE ON MEDICAL SERVICES OF THE ARMED FORCES

On January 12, Mr. Forrestal, Secretary of Defense, released a part of the report of the Committee on Medical Services of the Armed Forces, known as the Hawley Board, which has been studying these services for many months. The members of the committee, in addition to Gen. Paul Hawley, include Maj. Gen. R. W. Bliss, Surgeon General of the Army; Admiral Clifford A. Swanson, Surgeon General of the Navy; Maj. Gen. Malcolm C. Grow, Surgeon General of the Air Force, and Admiral J. T. Boone. The portion of the report thus far released concerns programs for hospitalization in the armed forces and for improvement in the utilization of existing hospital facilities. Much time has been given to studying the existing hospitalization The recommendations concern the actual details of utilization of many Army, Navy and Air Force hospitals. Actually the committee makes 71 specific recommendations for reducing and eliminating military hospitalization in the United States. Many of the recommendations concern patients who are now transferred from dispensaries or station hospitals to general hospitals of their own service or to general hospitals of another service. Such transfers will minimize the number of beds required and, coincidentally, of course, the number of physicians and other trained hospital personnel necessary for the conduct of an adequate service. The committee recommends the retention of 11 Army and 26 Navy hospitals in the United States and their continued use as general hospitals. Many of these are on Army or Navy reservations and function also as station hospitals. Detailed recommendations are made for the consolidation of hospitals in Panama, Trinidad, Puerto Rico, Cuba, Bermuda, Germany, Hawaii, Kwajalein, Alaska, Guam and Saipan. Without doubt, effective implementation of the recommendations of the committee will result in a great saving in personnel and funds without lowering in any way the standards of hospital care for members of the armed forces.

# ORGANIZATION SECTION

## Rural Health

The Board of Directors of the American Farm Bureau Federation, a member of the Advisory Committee to the Committee on Rural Health of the American Medical Association, unanimously adopted the following statement at its annual convention in Atlantic City, N. J., Dec. 16, 1948:

The quality of American medical service is very high. Unfortunately, American medical service at its best reaches only a relatively small part of the rural areas of the country. The shortage of physicians, hospitals and other medical facilities in the rural areas is not due to less need for medical care than in cities. The primary factors which most influence adequate medical facilities and which attract physicians are community environment and economic opportunity.

There is a wide gap between existing medical knowledge and the health practices in many rural areas. Rural people must first know their existing facilities and whether or not they are adequate. They must know the meaning of high standards in hospital and medical care. They must be taught the advantages of budgeting the costs of medical need as they do other household expenses. They must know the significance of health hazards around the farm home as they pertain to disease, including the relationship between animal diseases and human health. They must know what services offered by public and voluntary agencies are available to them, and they must discover their own health needs and formulate their own program.

For this reason we heartily commend the health programs already under way in some of our State Farm Bureaus, and urge other states to follow as soon as practicable. We also recognize promise in the long range health education program carried on by the Agricultural Extension Service. We urge the Land-Grant colleges to expand this program to the extent that they have an extension health education specialist on their staffs.

We suggest that our State Farm Bureaus give serious consideration to the desirability and possibility of offering scholarships whereby physicians, surgeons, dentists and nurses will be encouraged to establish themselves in rural areas. We believe the problem of improved health can best be met by the voluntary organizations of cooperative health associations which will encourage people to take advantage of the services available for any medical or dental care which they may require.

We stand ready to cooperate with the Rural Health Committee of the American Medical Association and other groups in providing better voluntary medical care for rural people. We urge the continued interest and cooperation of the states in cancer, tuberculosis, venereal disease, poliomyelitis, crippled children, heart and rheumatic fever programs. We also endorse the American Red Cross National Blood Program and recommend active participation by our Farm Bureau members. We favor voluntary plans providing medical,. health, dental and hospital insurance. We urge that facilities of medical schools be expanded, and every effort be made otherwise to train more physicians, surgeons, dentists, nurses, technicians and general practitioners and public health doctors. We recommend the full cooperation of rural people with our established health units and existing health programs, including immunization, clinics, nutrition courses and home nursing. We believe greater emphasis should be given to preventive medicine. We suggest that in the states where permissive legislation for the creation of public health units does not exist, state farm bureaus secure the enactment of such legislation.

We favor reasonable appropriations for grants-in-aid to states for maternal and child health programs, and also to assist states in the expansion of needed public services and facilities. To the extent federal grants are needed by way of assistance, such grants should be made to states on the basis of need, with state governments responsible for the allocation and administration of these funds.

The American Farm Bureau Federation has consistently supported the Hill-Burton Hospital Construction Act, and we will support the continuation of this Act and appropriations necessary to achieve the objectives of the law. The American Farm Bureau Federation urges the state farm bureaus to cooperate in the administration of the Act in their respective states. In the administration of the Act, agriculture must have adequate representation on national and state advisory councils.

## Washington Letter

*(From a Special Correspondent)*

Jan. 24, 1949.

### Hawley Board Report Coincides With Successor's First Meeting

The first meeting of the new Armed Forces Medical Advisory Committee was held January 11-12, coincident with the release by Secretary of Defense Forrestal of the most comprehensive report yet submitted by the Hawley Board. The latter, known officially as the Committee on Medical and Hospital Services of the Armed Forces, is due to be dissolved in the near future and its functions assumed by the new advisory group, whose chairman is Charles Proctor Cooper of New York. At its first session, held in the Pentagon, the myriad problems confronting the military medical departments—man power, consolidation of facilities, postgraduate education and others—were discussed but no action was taken. A subcommittee was appointed to draw up plans for organization and procedures and report to the committee's next meeting, scheduled for February 24-25. Its members are Maj. Gen. Raymond W. Bliss, Army Surgeon General; Drs. M. C. Pincoffs and Edward D. Churchill, and Mr. Cooper, committee chairman.

The Hawley Board report proposes closing of three large general hospitals (two Army and one Navy); recommends joint staffing by Army and Navy personnel of all hospitals that are used in common by members of the armed forces; urges joint utilization of civilian consultants and specialists; favors consolidation and common use of specialty treatment and rehabilitation centers, as in neuropsychiatry and tuberculosis, and looks askance at utilization of civilian, nonmilitary institutions for hospitalization of service men.

General hospitals suggested for closing are McCornack General at Pasadena, Calif., and the 22nd (Army) General, Guam, where adequate naval facilities are available, and the naval hospital at Honolulu, whose patient load would be absorbed by the Army's new Tripler General Hospital. Three other Army general hospitals would be reduced to station hospital status: 183rd at Anchorage, Alaska; Fort Totten, on Long Island, and Tilton, at Camp Dix, N. J. In addition, the Hawley Board urged reduction of forty-eight smaller station type medical facilities to the status of dispensaries (giving outpatient care only). Secretary Forrestal, in making the 75 page report public, emphasized that it has not yet been approved or reviewed by him. He added that "the character of the recommendations clearly indicates that important progress is being made toward effective coordination of the military medical services."

### Rules Liberalized on Immigration of Refugee Physicians

The Displaced Persons Commission has modified certain regulations on admittance into the United States of "DP's" who are licensed physicians, following receipt of numerous letters protesting that it is difficult for the sponsoring organization to state exactly where the prospective immigrant will reside or be professionally engaged.

Henceforth, recognized voluntary and public agencies and institutions, when submitting assurances in behalf of displaced persons who are licensed physicians, will not be required to specify where the subject will live or the place where he will work. The sponsoring agency is obliged to report to the Commission every six months with reference to the physician's resettlement; that is, where he is residing and whether he is practicing his profession. The new type of blanket assurance will be accepted only from recognized voluntary and public agencies. Individual sponsors of displaced physicians are still required to furnish the more specific assurances.

According to a statistical study which will be included in the Displaced Persons Commission's report to Congress in early February, only 2 per cent of the first 19,500 assurances received were in behalf of professional men and women in medical, public health and allied fields, physicians, dentists and nurses chiefly. The ratio was even less with respect to semiprofessional persons in the same field.

# Medical Legislation

## STATE LEGISLATION

### Idaho

**Bill Introduced.**—H. 20, to amend the workmen's compensation act, proposes to authorize the **industrial accident board** to order an examination of the injured employee by a qualified physician selected either by the employee or by the board at the expense of the parties or as a charge against the industrial adminstration fund.

### Illinois

**Bill Introduced.**—S. 11 proposes the establishment of an Illinois State **Cancer Hospital** for the care and treatment of persons afflicted with cancer and an appropriation of $5,000,000 for the construction, operation, maintenance and equipping of such hospital.

### Maryland

**Bills Introduced.**—H. 5 proposes to require physicians, hospitals, nurses, etc., to **report to the sheriff** or state police the treatment of any person for an injury or for an act of violence under circumstances not presently known, giving the person's name and address, a description of the injury and any other facts concerning the affair which might assist in the detection of crime. S. 15 proposes the creation of a **Commission on Alcoholism** to establish and supervise clinics throughout the state for the treatment of persons afflicted with alcoholism and especially with chronic alcoholism. S. 16 proposes the creation of an **anatomy board** to have charge of the distribution of certain dead bodies which come under its control. Such bodies shall be used only for the promotion of the medical sciences. S. 23 proposes regulations for the licensing of **mental hospitals** throughout the state.

### Michigan

**Bills Introduced.**—H. 1 proposes the creation of a division of **professional and vocational licensing** to have the powers and duties formerly devolved upon, among others, the Board of Examiners of Basic Sciences, the Board of Chiropractic Examiners, the Board of Registration in Medicine and the State Board of Osteopathic Registration and Examination. S. 12 proposes the creation of a new department to be known as the **department of labor and industrial relations** and, among other things, creates a workmen's compensation and an unemployment compensation appeal board.

### Minnesota

**Bill Introduced.**—H. 22 proposes certain amendments to the law requiring physicians to report to the state board of health the names of persons placed under their care for the **treatment of tuberculosis.**

### Montana

**Bill Introduced.**—H. 9 proposes the enactment of a Montana Unemployment Compensation Disability Law to compensate in part for the **wage loss** sustained by individuals unemployed because of sickness or injury.

### Nebraska

**Bill Enacted.**—Legislative Resolution 2, passed January 10, memorializes the Congress of the United States to refrain from imposing upon the citizens of the nation **any form of compulsory insurance** or any system of medical care designed for national bureaucratic control.

### New York

**Bills Introduced.**—A. 49, to amend the education law relating to the issuance of certificates to ophthalmic dispensers, proposes to authorize the granting of such certificates without examination to persons who have been continuously conducting their own business in which they are engaged in **ophthalmic dispensing for at least fifteen years.** A. 92 and S. 64 propose to make it unlawful for any **public or semipublic hospital,** supported wholly or partly by public funds, to refuse to permit any physician or surgeon duly licensed by the state to diagnose, treat or operate on any patient in such hospital or to refuse admission to any hospital of any patient who has been recommended to be sent to or who has been sent to any such hospital by any such licensed physician or surgeon. A. 136 proposes an appropriation of $2,500,000 to defray the cost of **research in the cause and cure of cancer.** A. 276 proposes an appropriation of the sum of $2,000,000 toward the cost of **milk and lunches** furnished to children in the elementary and secondary public schools of the state. S. 1 proposes the enactment of a **disability compensation law.** S. 52 and A. 88, to amend the law relating to the medical examiner of Westchester County, propose to authorize the appointment of a **pathologist-medical examiner** to have charge of a newly created department of laboratories and research. The pathologist-medical examiner shall be a pathologist and microscopist experienced in his profession and shall meet such minimum qualifications of professional and administrative education and experience as may be required by the public health council of the state of New York. S. 94 proposes to authorize the use of the **injunctive process** in the enforcement of the medical practice act.

### Oklahoma

**Bill Introduced.**—H. 54, to amend the hospital licensing law, proposes to exempt therefrom any place maintained primarily for the purpose of providing a home or place to live for **indigent aged persons.**

### Rhode Island

**Bills Introduced.**—H. 507 proposes to authorize the appointment of a chief medical examiner to **perform all autopsies** and act as state pathologist. Such person would be required to be a doctor of medicine, qualified in pathology, with at least one year of medico-legal training. The medical examiner would, under the proposal make examinations on the bodies of such persons only as appear to have met their death from violence, or suddenly when in apparent good health, or when unattended by a physician or in any suspicious or unnatural matter or as the result of an abortion or suspected abortion. H. 513 proposes the enactment of a Rhode Island **Cash Sickness Compensation Act.** This appears to be a complete revision of the law enacted in 1942.

### Tennessee

**Bill Introduced.**—H. 182 proposes to authorize the granting of divorces **on the ground of incurable insanity.** The insanity must be certified by three physicians who are well recognized authorities on mental diseases, one of whom is the superintendent of the institution in which the insane party is committed and the other two of whom are appointed by the court before whom the action is pending.

### Utah

**Bills Introduced.**—H. 11, to amend the law relating to **physical examinations of employees,** proposes that an employer shall not require any employee or person applying for employment to submit to or obtain a physical examination unless the employer pays all costs and expenses incident thereto. S. Res. 1 proposes a Senate resolution memorializing the Congress of the United States to defeat any legislation introduced in Congress which provides for socialized medicine or **national compulsory health insurance** and which will result in a destruction of private initiative and free enterprise system in this country. S. 30 proposes the creation of a **state board on alcoholism** to cooperate with the Utah State Committee for Education on Alcoholism and to provide educational material such as visual aids, educational bulletins, etc., in the conduct of the educational program of such committee. S. 51, to amend the law relating to a definition of the practice of optometry, would include within such definition the prescription or adaptation of **contact lenses,** visual training and orthoptics. S. 56, to amend the law relating to the duplication of ophthalmic lenses, proposes to make it unlawful for any person other than the registered optometrist to accept or offer to accept for purposes of duplication any **ophthalmic lens** ordinarily used by the human eye for corrective purposes. S. 57 proposes to require any agency of the state, county or municipality to accept the **services of optometrists** registered in the state for the purposes of diagnosing and correcting any and all visual, muscular, neurologic and anatomic "neuralics" of the human eye and their appendages of any persons under the jurisdiction of such agency or governmental unit.

# Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Chicago, Palmer House, Feb. 7-8. Dr. Donald G. Anderson, 535 N. Dearborn St., Chicago 10, Secretary.

National Conference on Rural Health, Chicago, Palmer House, Feb. 4-5. Dr. F. S. Crockett, 535 N. Dearborn St., Chicago 10, Chairman.

Alaska Territorial Medical Association, Juneau, March 3-5. Dr. William P. Blanton, Box 2569, Juneau, Secretary.

American Academy of General Practice, Cincinnati, Netherlands Plaza Hotel, March 7-9. Mr. Mac F. Cahal, 231 W. 47th St., Kansas City, Mo., Executive Secretary.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, New York, Hotel Waldorf-Astoria, March 4. Dr. Norman N. Smith, 291 Whitney Ave., New Haven 11, Conn., Secretary.

Central Surgical Association, Cleveland, Hotel Cleveland, February 18-19. Dr. Walter G. Maddock, 250 E. Superior St., Chicago 11, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, Palmer House, March 1-4. Dr. H. Kenneth Scatliff, 30 N. Michigan Ave., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 14-17. Miss Thelma Webb, 1133 Medical Arts Bldg., Dallas, Executive Secretary.

National Conference on Medical Service, Chicago, Palmer House, February 6. Dr. John S. Bouslog, 1612 Tremont Place, Denver Colo., Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Municipal Auditorium, March 7-10. Dr. W. D. Beacham, 1430 Tulane Ave., New Orleans, Secretary.

# GOVERNMENT SERVICES

## ARMY

### CIVILIAN CONSULTANTS PROGRAM TO BE CONTINUED

The Surgeon General has announced that the Army Medical Department will continue the civilian consultants program during 1949. The program, which consists of sending teams of civilian specialists each month to Army and Navy hospitals in Europe, the Far East and the Panama Canal Zone, has been so successful that it may be retained as a permanent part of the Medical Department's operations. The consultants are chosen through the efforts of the Society of Medical Consultants of World War II, subject to approval by the Surgeon General. Each consultant must have outstanding abilities as a teacher, be certified by the specialty board in his field and preferably have had military service as medical officer. Three teams of consultants will leave the United States in January. The following European team will spend most of its time in Germany: Dr. William J. Stewart, associate professor of orthopedic surgery, University of Missouri Medical School, Columbia, and Dr. J. Gardner Hopkins, professor of dermatology, College of Physicians and Surgeons, New York.

The team going to the Far East Command will spend two days at Tripler General Hospital, Hawaiian Islands. After visiting the hospitals in Japan, the team will divide in order to have at least one member visit each Medical Department installation in the Philippine Islands, Guam, Okinawa and Korea.

In Panama, the team will conduct clinics at Gorgas General Hospital and at other Army and Navy hospitals.

The other teams are composed of the following physicians:

Far East Command: Dr. I. William Nachlas, assistant professor of orthopedic surgery, Baltimore; Dr. Irving Rush, associate professor of otorhinology, Temple University Medical School, Philadelphia, and Dr. Frederick W. Fitz, assistant professor of medicine, Northwestern University School of Medicine, Chicago.

Canal Zone: Dr. Donald A. Miller, practice of surgery, Warren, Ohio; Dr. Derrick Vail, professor of ophthalmology, Northwestern University School of Medicine, Chicago, and Dr. Harry Most, director, postgraduate course in tropical medicine, New York University–Bellevue Medical Center, New York.

### THE ARMY'S EDUCATIONAL PROGRAM

This program operates under the policy guidance of a committee of eleven civilian educators and two representatives from each of the educational divisions of the three military services. The Army's education program centers in the United States Armed Forces Institute (USAFI), which is located in Madison, Wis. The Institute provides the services with correspondence courses, self study courses, group study materials, subject tests, end of course tests, G. E. D. tests, lesson service and guidance. It also provides the serviceman's home town school with detailed records of his accomplishments and recommends the credit to be allowed. This program is currently recognized in forty-six states and the District of Columbia. The armed forces do not award credits, diplomas or degrees.

Brigadier General C. T. Lanham, Assistant to the Chief of Staff, in an address before the National Council for Social Studies in Chicago November 25, said that more than 50,000 men are now regularly attending these classes which are conducted on off-duty hours by part time instructors from neighboring educational institutions. The overseas educational centers are staffed by full time instructors from the United States, and the educational programs run the full spectrum from literacy training through graduate study.

In maintaining this program after the war, General Lanham said, "Thousands of men who had enlisted in the Army to escape from school have been encouraged to resume their studies and have gone on to win their high school diplomas and begin college-level work. These are matters of great moment to the Army and of great significance to our country. It would be unfortunate, indeed, if this program were ever abandoned, for, in point of fact, dollar for dollar our educational program provides our country with one of the most profitable investments it can make in its Armed Forces. It provides us with an alert soldiery; it pays rich dividends in terms of prestige for the man in uniform; it is one of the primary inducements in attracting high quality volunteers; and, it represents a permanent social gain to the Republic. The doors of the Army are open and a clean, invigorating wind is blowing away the cobwebs of a narrow and fruitless traditionalism. The good start that has been made cannot be continued without the interest, understanding and support of the American people."

### ADDITIONAL CONSULTANTS TO MEDICAL DEPARTMENT

The following civilian physicians had been added to the consultant list of the Army Medical Department as of November 1, 1948:

| Name and Residence | Hospital | Specialty |
|---|---|---|
| Dorothy Goetze<br>Hot Springs, Ark. | Army-Navy General Hospital | Dermatology and syphilology |
| Carroll F. Shukers<br>Little Rock, Ark. | Army-Navy General Hospital | Pathology |
| Herbert Davenport Jr.<br>Houston, Texas | Brooke Army Medical Center | Pathology |
| Robert K. Brown<br>Denver | Fitzsimmons General Hospital | Surgery |
| Emil Jobb<br>Seattle | Madigan General Hospital | Gastroenterology |
| Buford L. O'Neal<br>Atlanta, Ga. | Oliver General Hospital | Otolaryngology |
| J. Warren White<br>Norfolk, Va. | Oliver General Hospital | Surgery |
| Laurence M. Wiig<br>Honolulu, Hawaii | Tripler General Hospital | Surgery |
| Harry H. Shapiro<br>Boston | Army Medical Center | Anatomy |
| Walter R. Graham<br>Columbia, S. C. | Station Hospital, Fort Jackson, S. C. | Otolaryngology |
| Charles J. Lemmon Jr.<br>Columbia, S. C. | Station Hospital, Fort Jackson, S. C. | Surgery |
| Harvey M. Richey<br>Waco, Texas | Station Hospital, Camp Hood, Texas | Surgery |
| Stephen L. Johnson<br>Evansville, Ind. | Station Hospital, Camp Breckinridge, Ky. | Internal medicine |
| Fred M. Anderson<br>Reno, Nev. | Sierra Ordnance Depot, Herlong, Calif. | Surgery |
| Sol Z. Draznin<br>Cheyenne, Wyo. | Air Force Hospital, Fort Francis E. Warren, Wyo. | Radiology |
| Lloyd Brown<br>Bangor, Maine | Air Force Hospital, Dow Air Force Base, Maine | Surgery |
| Philip J. Kunderman<br>New Brunswick, N. J. | I Army Area | Surgery |
| John R. McCain<br>Atlanta, Ga. | III Army Area | Obstetrics and gynecology |
| Jules M. Key<br>San Francisco | VI Army Area | Dermatology and syphilology |
| Arturo L. Carrion<br>San Juan, P. R. | Medical Consultants Division | Dermatology |
| J. Gardner Hopkins<br>New York | Medical Consultants Division | Dermatology and syphilology |
| Henry M. Winans<br>Dallas, Texas | Medical Consultants Division | Internal medicine |
| J. Steward Rodman<br>Philadelphia | Education and Training Division | Surgery |
| Stanhope Bayne-Jones<br>New York | Historical Division, Army Medical Library | History of medical department in World War II<br>Preventive medicine |

### CERTIFIED BY BOARDS

The following medical corps officers have recently been certified by American Boards of their medical specialties: Colonels Samuel L. Cooke, otolaryngology; Frank Y. Leaver, diagnostic roentgenology, roentgen therapy and radium therapy; Henry S. Murphey, otolaryngology, and Paul O. Wells, radiology; Lieutenant Colonels Lester O. Crago, internal medicine; Robert J. Hoagland, internal medicine, and Byron E. Pollock, internal medicine, and Major Alfred A. Hellams, psychiatry.

# NAVY

## GRADUATE MEDICAL TRAINING PROGRAM

The following lieutenants (jg) in the Regular Navy Medical Corps have been nominated for their first duty to courses of instruction under the Navy's Medical Graduate Training Program: Edward F. Burkhart of Harlan, Ky., to continue as a resident in dermatology and syphilology at St. Mary's Group of Hospitals of St. Louis University; John B. Caire of New Orleans to a residency in obstetrics and gynecology at the Naval Hospital, Long Beach, Calif.; William J. Champion of Philadelphia to a residency in general surgery at the Naval Hospital, Naval Medical Center, Bethesda, Md.; Winfield D. Edgerton of Poplar Bluff, Mo., to a residency in obstetrics and gynecology at the Naval Hospital, Chelsea, Mass.; Samuel M. Fox III of Germantown, Pa., to continue instruction in a fellowship in internal medicine with emphasis on gastroenterology at the Hospital of the University of Pennsylvania, Philadelphia; Kenneth A. Parmelee of Stratford, Conn., to continue instruction in a residency in radiology at Bridgeport Hospital, Bridgeport, Conn.; Maxwell G. Potter of Syracuse, N. Y., to continue instruction in a residency in psychiatry at Philadelphia General Hospital; Anthony P Prezyna of Lackawanna, N. Y., to a residency in pathology at the Naval Hospital, Naval Medical Center, Bethesda, Md.; James H. Stewart of New Orleans to continue instruction as resident in pathology at Touro Infirmary, New Orleans, and Sam D. Waldrop of Tuscaloosa, Ala., to a residency in general surgery at the Naval Hospital, Naval Medical Center, Bethesda, Md.

## POSTGRADUATE INSTRUCTION

The following Naval medical officers have been nominated for postgraduate instruction as indicated: Comdr. Edward J. Jaruszewski, M.C., to a fellowship in internal medicine at Western Reserve University, Cleveland; Lieut. Comdr. Charles N. Scott, M.C.R., of Smithfield, W. Va., to instruction at the School of Aviation Medicine and Research, Pensacola, Fla.; Lieut. George C. Calderwood, M.C., of Roxbury, Mass., to a residency in obstetrics and gynecology at the Naval Hospital, Chelsea, Mass.; Lieutenants (jg) Maurice N. Johnson, M.C.R., of Minneapolis, to instruction at the School of Aviation Medicine and Research, Pensacola, Fla.; Myron E. Samuelson, M.C.R., of Genoa, Neb., to a residency in surgery at the Naval Hospital, San Diego, Calif., and Henry Santina, M.C.R., of San Francisco to instruction at the School of Aviation Medicine and Research, Pensacola, Fla.

## FIRST ACTIVE DUTY AS INTERNS

The following lieutenants (jg) in the medical corps reserve have reported for their first active duty as interns in the civilian institutions indicated, and on completion of their internships will serve in naval medical facilities:

| Name | Residence | Institution |
|---|---|---|
| Alexander, Merrill J. | Urbana, Ill. | Cook County Hospital, Chicago |
| Annesley, William H., Jr. | Philadelphia | Lankenau Hospital, Philadelphia |
| Behrhorst, Carroll D. H. | Brazilton, Kan. | St Louis City Hospital |
| Bowden, Ben W. | Munday, Texas | Shreveport Charity Hospital, Shreveport, La. |
| Cotthoff, John E. | Portland, Ore. | John Gaston Hospital, Memphis, Tenn. |
| Critz, George T. | Cincinnati | Christ Hospital, Cincinnati |
| Evans, James H., Jr. | New Holland, Pa. | Lancaster General Hospital, Lancaster, Pa. |
| Farrell, Gerald J., Jr. | Corona, N. Y. | Bridgeport Hospital, Bridgeport, Conn. |
| Foerster, Harry R., Jr. | Hartland, Wis. | Germantown Dispensary and Hospital, Philadelphia |
| Grice, Paul F. | Mulberry, Ind. | Hurley Hospital, Flint, Mich. |
| Guill, Russell E. | Kerrville, Texas | Santa Rosa Hospital, San Antonio, Texas |
| Hill, Billy J. | St. Paul, Neb. | King County Hospital, Seattle |
| Hoffman, Gilvert M. | Allentown, Pa. | Allentown General Hospital |
| Horn, Paul L., Jr. | Winston-Salem, N. C. | Charity Hospital of Louisiana, New Orleans |
| Keeler, Clifford E. | Jackson, Mich. | San Diego County General Hospital, San Diego, Calif. |
| Kircher, Robert W. | Norwalk, Conn. | Bellevue Hospital, New York |
| Krouse, Theodore B. | Philadelphia | Philadelphia General Hospital |
| Maddox, Stephen G., Jr. | Fort Worth, Texas | Baylor University Hospital, Dallas, Texas |
| Monahan, Thomas J., Jr. | Roslindale, Mass. | Boston City Hospital |
| Montgomery, Donald M. | Bexley, Ohio | Deaconess Hospital, Cincinnati |
| Nelson, Robert A. | Tulsa, Okla. | Ancker Hospital, St. Paul |
| O'Malley, Keven B. | Cynwyd, Pa. | Huron Road Hospital, East Cleveland, Ohio |
| Parsons, David W. | Louisville, Ky. | Presbyterian Hospital, Chicago |
| Philp, David R. | Mankato, Minn. | Northwestern Hospital, Minneapolis |
| Schmitthenner, Jerry E. | Chambersburg, Pa. | Lankenau Hospital, Philadelphia |
| Scott, Alfred W., Jr. | Athens, Ga. | Philadelphia General Hospital |
| Spence, David L. | Pittsburgh | Germantown Dispensary and Hospital, Philadelphia |
| Swartz, Curtis H. | Akron, Pa. | Lancaster General Hospital, Lancaster, Pa. |
| Wilson, Theodore W. | Marshall, Minn. | Minneapolis General Hospital |
| Zucca, John L., Jr. | San Francisco | Mary's Help Hospital, San Francisco |

# PUBLIC HEALTH SERVICE

## INFLUENZA EPIDEMIC IN EUROPE

Surgeon General Scheele states that the present epidemic of influenza in Europe is mild, causing few deaths, and that so far there is no indication that it may spread to the United States. The Public Health Service and the medical departments of the Army, Navy and Air Force are in constant touch with the situation through the Influenza Information Center (see The Journal, Jan. 8, page 108) at the National Institutes of Health. Influenza authorities in Europe cabled as of January 13 that the European epidemic had spread from Italy to Austria, France, Belgium and the Netherlands, with another focus in Czechoslovakia. The Director of the World Influenza Center in London, Dr. C. H. Andrewes, reported on that date that, while influenza virus B had been isolated in Italy, there was no certainty that this virus was the chief culprit, and that it had not yet been determined whether the viruses causing the outbreaks in Europe are similar to those in existing vaccine. Dr. Pierre Lepine of the Pasteur Institute in Paris cabled that one half of the influenza cases tested in Paris were caused by a type A virus, the other half by an unrelated virus strain or strains not yet identified. The influenza vaccine now commercially available includes three strains of virus, a type A virus known as PR-8, the Lee virus, which is a type B virus, and the FM-1 virus, which is an A virus.

The Influenza Information Center at Bethesda, Md., has requested all state and local health offices and local communicable disease control offices to report promptly every local outbreak of influenza in this country so that the Influenza Information Center may alert diagnostic laboratories in the region affected, asking them to make serologic tests for the presence of antibody against the influenza virus. Certain laboratories would also be asked to assign investigators to the affected community. Fifty-six diagnostic laboratories are participating in this part of the program.

## STUDY OF ENVIRONMENT IN CANCER

A research project to study the role of environment in cancer will be set up at Georgetown University Medical School, Washington, D. C., with funds provided by the National Cancer Institute. The financial aid to Georgetown will be for converting two large classrooms at the medical school into modern laboratory units. Facilities of the medical school will be used, but the work will be carried out by scientists of the National Cancer Institute. Dr. Wilhelm Hueper of the Institute will be in charge. Among environmental factors to be studied are the substances used by modern industry. State health officials will also be asked to make occupational cancer studies to aid in the project.

# Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

## COLORADO

**Lectures in Psychosomatic Medicine.**—A lectureship on psychosomatic medicine sponsored by the University of Colorado School of Medicine, Denver, is to be given at the university February 7-11. The guest lecturer is Dr. Douglas D. Bond, professor of psychiatry, Western Reserve University School of Medicine, Cleveland. All physicians licensed to practice medicine and who are members of county medical societies are invited to attend. A detailed program may be obtained from Dr. Franklin G. Ebaugh, Department of Psychiatry, University of Colorado School of Medicine, Denver.

## CONNECTICUT

**First Typhoid Case in Seven Years.**—The first diagnosed case of typhoid in New Haven in seven years occurred November 5 and resulted fatally November 16. This was the first recorded death from typhoid in the state for 1948. An investigation proved that the victim had eaten clams which had been dug from a posted area along the shore af New Haven harbor. None of the other guests at the dinner party where the clams were served were affected.

**Yale Alumni in Public Health.**—Yale alumni now active in public health work are planning to establish an organization to be known as Yale Alumni in Public Health, which will assist in formulating teaching plans, facilitate the exchange of ideas and promote improved professional standards. At the organization meeting held during the recent convention of the American Public Health Association in Boston, more than one hundred and fifty public health graduates, faculty and former faculty members heard the proposed constitution for the new group.

**Change in Board Membership.**—Dr. Thomas P. Murdock, chairman of the governing council of the Connecticut State Medical Society, has resigned as a member of the Connecticut Medical Examining Board and Dr. John H. Bumstead, New Haven, a graduate of Johns Hopkins University School of Medicine, Baltimore, 1923, has been appointed to fill the vacancy. Dr. Murdock had been a member of the Examining Board continuously for more than seventeen years, and served as its president since January 1948. Dr. Bumstead's appointment to the board was effective January 1 for a term of five years. He has practiced medicine in Connecticut since 1930.

## FLORIDA

**Personal.**—Roland B. Mitchell, Ph.D., has resigned as director of laboratories for the Florida State Board of Health to become head of the department of bacteriology at the School of Aviation Medicine, Randolph Field, Texas.

**State Health Department Report.**—Dr. Wilson T. Sowder, Florida state health officer, in making his yearly report listed the following advances for 1948. Approximately 21 per cent or 386,504 of the adult population were given roentgen examinations during the mass survey conducted in thirty-four counties. It is planned to survey 20 per cent of the population during 1949. Since a statewide stream pollution survey showed that a vast portion of streams and lakes were becoming dumping grounds for Florida wastes, plans were made for sewage treatment plants at the Universities of Miami and of Florida, Silver Springs, Milton, Lakewood subdivision and Jacksonville. Construction is under way on plants in three other cities, another three are ready to construct and several are being surveyed.

## GEORGIA

**Course in Allergy.**—The American Academy of Allergy in cooperation with the University of Georgia School of Medicine in Augusta will sponsor an orientation course in allergy from March 7 through March 11 at the university. This course is under the direction of Dr. Leo H. Criep, Pittsburgh, assisted by other fellows of the American Academy of Allergy and a distinguished faculty. Enrolment is open to any one interested, and the fee is $50. Applications should be addressed to the Executive Office of the Academy, 208 East Wisconsin Avenue, Milwaukee 2.

**Special Society Meeting.**—The annual meeting of the Georgia Society of Ophthalmology and Otolaryngology will be held in the General Oglethorpe Hotel in Savannah on March 4-5. The program is as follows:

Paul A. Chandler, Boston, Glaucoma Management.
Jack S. Guyton, Baltimore, Cataract Management.
Oscar C. E. Hansen-Pruss, Durham, N. C., Allergy of the Upper Respiratory Tract.
Marvin F. Jones, New York, Management of Ear Problems in Children and an Otological Survey.
Ralph O. Rychener, Memphis, External Eye Diseases and Dacrocystitis.
Fletcher D. Woodward, Charlottesville, Va., Problems in Laryngology.

## ILLINOIS

**Personal.**—Dr. Frank L. Rector of Evanston has been awarded the Navy Cross Medal for his service as medical officer with an infantry battalion in the Saipan and the Tinian engagements in the recent war. The award was made December 24 at the Swan Island Naval Base, Portland, Ore. The previously awarded Silver Star Medal (THE JOURNAL, May 12, 1945, page 136) was recalled by the Navy and in its place the Navy Cross Medal was awarded.

**Extend X-Ray Survey.**—The Tuberculosis Institute of Chicago and Cook County and the Municipal Tuberculosis Sanatorium are planning to give roentgen examinations to 350,000 persons in Chicago and Cook County in 1949. The two groups examined over 300,000 in the Chicago area last year. The program has already begun with surveys being made in three large Chicago area industries. Workers were allowed time off from their jobs to be examined in the mobile units.

### Chicago

**The Bacon Lecture.**—The Charles Sumner Bacon Lecture will be delivered at the University of Illinois February 23 at 1 p. m. by Dr. Edwin C. Hamblen, Durham, N. C., on "Postpubescent Amenorrhea."

**Heart Association Meeting.**—The Chicago Heart Association Clinical Section will hold a joint meeting with Presbyterian Hospital and the University of Illinois February 18 in Room 221 of the university's medical school from 10 a. m. to 12:15 p. m. Physicians are welcome.

**Diabetes Sixth Cause of Death.**—Diabetes ranked as the sixth cause of death in Chicago up to Dec. 6, 1948, according to the Chicago Health Department. On that date 1,132 deaths due to diabetes had been reported, a slight decrease from the 1,145 total for a corresponding period in 1947. The diabetes death rate for the year was computed as 33.3 deaths per 100,000 population as against 33.7 per 100,000 population for the same period in 1947.

**Annual Cancer Symposium.**—The second annual Cancer Symposium for Chicago Doctors will be held January 26 through April 8 from 9 a. m. to 4:30 p. m., sponsored by the Chicago Medical Society, the faculties and staffs of participating medical schools and hospitals and the Illinois Division of the American Cancer Society. The first meeting was held at Northwestern University Medical School January 26. The second meeting will be held February 16 at Mercy Hospital with Loyola University Medical School participating. On March 16 meetings will be held in the amphitheater, Sarah Morris Children's Hospital of Michael Reese Hospital. The fourth series of lectures will be given April 6 at the University of Illinois College of Medicine, and the last of the symposium lectures will be delivered in the morning of April 8 at the University of Chicago Medical School.

**Fifth Annual Clinical Conference.**—The fifth annual Clinical Conference of the Chicago Medical Society will be held at the Palmer House March 1-4. The fee is $5. The program is as follows:

John W. Harris, Madison, Wis., Bleeding in the Last Trimester of Pregnancy.
Robert L. Jackson, Iowa City, Treatment of Rheumatic Fever and Prevention of Recurrences.
Walter P. Blount, Milwaukee, Fractures in Children Are Different.
Charles B. Huggins, Chicago, Diagnosis of Testicular Tumors.
Wendell G. Scott, St. Louis, Diagnosis of Congenital Heart Disease by Angiography and Aortography.
William L. Benedict, Rochester, Minn., Ocular Manifestations in Systemic Diseases.
Roscoe L. Sensenich, South Bend, Ind., Dangers to the Public in Socialized Medicine.
Walter C. Alvarez, Rochester, Minn., Puzzling Functional Syndromes.
Paul C. Bucy, Chicago, Fractures of the Skull.
LeRoy H. Sloan, Chicago, Causes of Low Back Pain in the Older Patient.
Bernard J. Alpers, Philadelphia, The Sciatica Problem.
Ovid Meyer, Madison, Wis., Recent Developments in Anticoagulant Therapy.
Marion A. Blankenhorn, Cincinnati, Treatment of Pneumococcal Pneumonia with Single Daily Dose of Penicillin.
Charles T. Stone, Galveston, Tex., Infectious Hepatitis.
George M. Lewis, New York, Recent Advances in Dermatologic Therapy.
Everett I. Evans, Richmond, Va., Fluid and Electrolyte Requirements in Surgery.

Willis J. Potts, Chicago, Diagnosis and Surgical Treatment of Patent Ductus Arteriosus.
Albert C. Furstenberg, Ann Arbor, Mich., Antibiotics in the Treatment of Diseases of the Ears, Nose and Throat.
Thomas E. Jones, Cleveland, Carcinoma of the Colon.
Henry W. Woltman, Rochester, Minn., Influence of Arteriosclerosis on the Central Nervous System.
Leo G. Rigler, Minneapolis, Minn., Roentgen Diagnosis of Carcinoma of the Lung.
John L. Emmett, Rochester, Minn., Surgical Treatment of Urinary Retention.
William D. Stroud, Philadelphia, Coronary Thrombosis.
William A. Altemeier, Cincinnati, Chemotherapy in Surgery.
Archibald D. Campbell, Montreal, Canada, Damaged Birth Canal and Its Repair.
James L. Poppen, Boston, Intracranial Aneurysms.
Louis R. Limarzi, Chicago, Thrombocytopenic Purpura.
Arthur A. Schaefer, Milwaukee, Surgical Problems in Pediatrics.
Ray Farquharson, Toronto, Canada, Diagnosis and Treatment of Common Anemias.
Barney Brooks, Nashville, Tenn., Surgery in the Aged.
Harry M. Weber, Rochester, Minn., Diagnosis of Early Intestinal Cancer.
Robert W. Keeton, Chicago, Objectives in the Treatment of Diabetes Mellitus.
James J. Callahan, Chicago, Fractures of the Hip.
Edmund F. Foley, Chicago, Diagnosis and Treatment of Early Pulmonary Tuberculosis.

## IOWA

**Business Men Honor Physician.**—The Alta Chamber of Commerce feted Dr. John W. Morrison, who had practiced medicine in that city since 1904, at an anniversary party in December attended by several hundred friends. A watch was presented to Dr. Morrison and a gift of over $2,500, which will be used to purchase equipment for the new Alta Memorial Hospital, which Dr. Morrison has been promoting.

**Information Wanted on Early Schools.**—Any person having first hand information regarding some of the early schools of medicine in Iowa is asked to communicate with Dr. John T. McClintock, Room 259, Medical Building, Iowa City, for the purpose of completing information on the history of medical education in the state. Information is sought on the following schools particularly: King Eclectic Medical College of Des Moines for the period 1880 to 1886; Iowa Eclectic Medical College about the same time; Council Bluffs Medical School, 1893 to 1895; a proposed school at Colfax in 1886, and the proposed W. F. Peck School at Davenport, 1896.

## MAINE

**Mt. Desert Island Laboratory.**—The Mt. Desert Island Biological Laboratory, Salisbury Cove, Maine, is offering its facilities for research in the study of biology for the season of 1949. The recent fire caused no damage to the laboratory. There is also a newly equipped laboratory for the study of problems in tissue growth under the supervision of Philip R. White, Ph.D., to whom individuals should address their inquiries at the Institute for Cancer Research, Girard and Corinthian Avenues, Philadelphia 30. In memory of Ulric Dahlgren, long one of the guiding spirits of the laboratory, a gift has been received for the establishment of research fellowships. The number and value of the fellowships cannot be stated now, but will be sufficient substantially to defray some of the expenses. Mature investigators will receive first consideration. Inquiries, except those noted, should be addressed to Dr. J. Wendell Burger, director of Trinity College, Hartford 6.

## MARYLAND

**Personal.**—Dr. F. Kenneth Albrecht, Baltimore, has resigned as medical editor of the Williams and Wilkins Company, Baltimore, and has been appointed director of the Division of Tuberculosis Control, Kansas State Board of Health, Topeka, Kan.

**Dr. Pfund Dies.**—August H. Pfund, Ph.D., professor emeritus of physics, Johns Hopkins University, Baltimore, and an authority on physical optics and infra-red rays, died in Baltimore, January 5, aged 69. He was a recipient in 1939 of the Frederic E. Ives medal of the Optical Society of America.

## MICHIGAN

**Dr. Clark Appointed Emeritus Professor.**—Dr. Harry L. Clark, after nearly forty years' association with Wayne University, has been appointed emeritus professor of bacteriology and clinical pathology. He joined the faculty in 1919 and has held the rank of professor of bacteriology and clinical pathology since 1922.

**Case-Finding Survey at County Fairs.**—Mobile chest x-ray units of the Michigan Department of Health, conducting a case finding survey in twenty-seven county fairs last summer and fall discovered 693 cases of suspected active or healed tuberculosis. Among the 42,324 persons given roentgen examinations, 1 suspect case was found for every 61 persons examined.

In 1947 a total of 43,670 persons was examined roentgenologically at twenty-three fairs, revealing 418 cases of suspected tuberculosis, or an average of 1 case for every 104 persons examined. The 1948 fair survey found 1,879 chest abnormalities, but additional follow-up showed that about two thirds of these were due to causes other than tuberculosis.

## MISSOURI

**Personal.**—Dr. J. Earl Smith, St. Louis, has been appointed St. Louis City Health Commissioner to fill the vacancy created by the death of Dr. Joseph F. Bredeck on Oct. 4, 1948. He is a graduate of St. Louis University School of Medicine.

**Annual Barnard Lecture.**—The annual Barnard Lecture is to be given at the St. Louis Medical Society Auditorium in St. Louis, February 1 by Dr. Herbert F. Traut, professor of obstetrics and gynecology at the University of California Medical School, Berkeley–San Francisco. The title of the lecture will be "Cytological Diagnosis of Cancer as It Applies to the Female Genital and Pulmonary Tracts."

## NEW JERSEY

**Joins Foundation Staff.**—Dr. Robert J. Neville of Teaneck, N. J., will join the medical staff of the National Foundation for Infantile Paralysis on February 15. From 1936 to 1942 he was a member of the orthopedic service of the New York Postgraduate Hospital, and also served from 1938 to 1942 as instructor in orthopedic surgery at New York Post-Graduate Medical School, Columbia University. During the succeeding five years Dr. Neville was a staff member of New York Orthopaedic Dispensary and Hospital. He is also a member of the orthopedic staff of Bergen Pines Hospital, Bergen County, Oradell, N. J., which specializes in the treatment of acute and chronic poliomyelitis cases.

## NEW YORK

**Newspaper Articles on Medical Practice.**—As a means of keeping readers informed on Nassau County medicine and establishing a better understanding of medical problems, the Public Relations Committee of the Nassau County Medical Society is sponsoring a series of articles in the local press. These articles appear under the name of the chairman of the Public Relations Committee.

**Postgraduate Instruction.**—The Medical Society of the State of New York in cooperation with the New York State Department of Health has arranged a postgraduate lecture for the Glens Falls Academy of Medicine on March 17 at 8:30 p. m. at the Glens Falls Library. Dr. Bradley L. Coley, New York, will speak on "Diagnosis and Treatment of Bone Tumors." The Schenectady County Medical Society on February 1 at 8:30 p. m., meeting in the Eastern New York Orthopedic Hospital in Schenectady, will hear Dr. Cushman D. Haagensen, New York, speak on "Cancer of the Breast."

### New York City

**Society Elections.**—The Brooklyn Dermatological Society has chosen as officers for 1948 and 1949 Dr. Ernest A. Gauvain, president, and Dr Samuel I. Greenberg, secretary-treasurer. ——At the December meeting of the Brooklyn Urological Society, Dr. Lawrence L. Lavalle was elected president and Dr. Mark Fishberg secretary-treasurer.

**The Largest Postgraduate Enrolment.**—The annual meeting of the Joint Committee of Postgraduate Education of the Long Island College of Medicine and the Medical Society of the County of Kings was held January 4 in Brooklyn. During the last calendar year, sixty-four courses were given and were attended by 1,094 doctors, the largest enrolment ever recorded by the committee since it began its postgraduate courses in 1923.

**Tuberculosis Conference.**—A clinical session on chronic pulmonary diseases has been planned for the Tuberculosis Sanatorium Conference of Metropolitan New York February 9, at 8:15 p. m. at the Cornell University Medical College Amphitheater. Dr. John N. Hayes, New York, will speak on "The Present Status of Pneumothorax," Dr. Robert S. Mitchell, Trudeau, on "The Present Status of Phrenic Nerve Interruption in the Treatment of Pulmonary Tuberculosis" and Dr. Ralph E. Moyer on "The Value of Pneumoperitoneum in the Treatment of Pulmonary Tuberculosis."

**Dr. Kogel Named Commissioner of Hospitals.**—Dr. Marcus D. Kogel, general medical superintendent of the department of hospitals, has been named commissioner of hospitals effective February 1, succeeding Dr. Edward M.

Bernecker, recently resigned. Dr. Kogel is a graduate of the New York Homeopathic Medical College and Flower Hospital, 1927, and served in the Medical Corps of the U. S. Army through 1929 and 1930. He became deputy medical superintendent of Cumberland Hospital, then medical superintendent of the hospital and of the Brooklyn Cancer Institute. He was the first medical superintendent of Queens General Hospital in Jamaica in 1935. He assumed his present position of general medical superintendent in the department of hospitals in October 1946.

**Eight Millions for Postgraduate Education.**—A gift "in excess of $8,000,000" from the Samuel H. Kress Foundation has been made to the New York University-Bellevue Medical Center. Terms of the grant stipulate that it is to be devoted to the development at the center of a program of postgraduate medical education which will be national and worldwide in its scope and which will require a decade to work out on a constructive basis. About $4,000,000 will be made available as capital funds for the construction of postgraduate facilities in the new buildings, and a second $4,000,000 will be earmarked as a support for a program of postgraduate medical teaching by outstanding practicing physicians and surgeons. The gift follows by less than two months the announcement by the university of the formation of a new postgraduate medical school into which has been incorporated the program and properties of the New York Postgraduate Medical School and Hospital (THE JOURNAL, Dec. 11, 1948, p. 1105).

## NORTH CAROLINA

**Typhoid Cases Increase.**—The North Carolina State Board of Health reports that for the first time since 1935 there was an increase in the number of typhoid cases reported in the state, the total for 1948 having been 62 as compared with 48 in 1947. Infantile paralysis cases numbered 2,518 during 1948 as compared with 300 in 1947. Diphtheria cases were at an all time low with 519 during 1948 as compared with 751 during 1947. Previous low was 590 cases reported for 1946.

**Medical and Surgical Symposium.**—The sixth annual Medical and Surgical Symposium of Watts Hospital, Durham, will be held February 16-17 in the Carolina Theater. The program is as follows:

Paul D. White, Boston, The National Heart Institute and the National Advisory Council.
Priscilla White, Boston, Management of the More Difficult Cases of Diabetes Complicating Pregnancy.
Henry T. Ricketts, Chicago, Modern Trends in Diabetes.
William Dameshek, Boston, The Spleen and Hypersplenism.
H. Houston Merritt, New York, Experimental Approach to the Treatment of Convulsive Disorders.
Rudolph A. Bartholomew, Atlanta, Ga., The Implications of Vascular Disease in Pregnancy.
Hugh R. Butt, Rochester, Minn., Evaluation of Current Tests for Liver Function.
Charles L. Short, Boston, Diagnosis of Rheumatoid Arthritis.
Chester M. Jones, Boston, Nutritional Disturbances Associated with Anastomotic Surgery of the Gastro-Intestinal Tract.
Robert E. Gross, Boston, Treatment of Coarctation of the Aorta.

The program Wednesday night will be a panel discussion on cardiovascular disease under the chairmanship of Dr. White, with William B. Porter, Richmond, Va.; Edward S. Orgain, Durham, N. C.; Edwin S. Wood Jr., Charlottesville, Va.; Dr. Gross and Elexious T. Bell, Minneapolis, taking part.

## OHIO

**Toledo Bureaus Merged.**—Toledo has established a city Bureau of Preventative Medicine, merging communicable disease work with venereal disease control. The move was necessary from the standpoint of economy and the fact that the state of Ohio, after the first of the year, planned to abandon its venereal disease control work in Toledo. Dr. Cornelius J. A. Paule of the state department was to be named head of the combined bureau.

**Cerebral Palsy Center.**—A cerebral palsy center is to be opened next fall in the Speech Building now under construction at Bowling Green (Ohio) State University. It is to be a cooperative project of the university and the Ohio Society for Crippled Children. The university will provide supervisory personnel, quarters, maintenance and use of testing and recording equipment now on hand. The Ohio society will provide funds for a speech, physical and occupational therapy and such special equipment as may be needed. It has allocated $15,000 a year for a three year period from its James T. Pardee Fund for special service projects, and will also provide medical and other professional consultants as needed and special postgraduate training in cerebral palsy for therapists who will be on the center's staff. Dr. Winthrop M. Phelps, Baltimore, Md., will become consultant to the center through the Ohio society.

## TEXAS

**Society News.**—The Waco Pediatrics Society was organized in September, with Dr. Margil C. Carlisle as president and Dr. F. William Hoehn as secretary. The ultimate aim of the organization is reported to be the construction of a children's hospital in Waco.

**University Appointment.**—Dr. Marshall H. Brucer, recently appointed director of the Biology Division of the Oak Ridge (Tenn.) Cancer Research Laboratory under the auspices of the Atomic Energy Commission, has been appointed visiting professor of physiology at the University of Texas Medical Branch, Galveston. This appointment has been made in order to enable Dr. Brucer to supervise the completion of research undertaken at the Medical Branch before his appointment to the Oak Ridge Laboratories.

**Free Cerebral Palsy Treatment.**—The Dallas Society for Crippled Children is operating a cerebral palsy treatment center for children at no cost to their families. The medical staff is composed of twelve doctors whose service is free of charge. The doctors also give courses for parents and a series of fifteen lectures which explain the cause of cerebral palsy and treatment. Operating funds come from the sale of Easter Seals, the Dallas Junior League and miscellaneous donations. Three nurses' training schools in Dallas, the Southwestern Medical College and Southern Methodist University Medical Department send their students to the center to work.

## WASHINGTON

**Bainbridge Island Honors Physician.**—More than 400 residents of Bainbridge Island turned out recently at Winslow to pay tribute to Dr. Frank L. Shepard. The Bainbridge Chamber of Commerce sponsored the affair in tribute to Dr. Shepard's service to island residents since his arrival in 1911. More than 75 friends and representatives of island groups met at dinner in the town hall. Later the party moved to the Bainbridge High School, where a larger group attended the ceremonies.

## WISCONSIN

**Personals.**—The degree Doctor Honoris Causa was awarded by the National University of San Marcos in Lima, Peru, to Dr. Arthur L. Tatum, professor of pharmacology at the University of Wisconsin Medical School, last September. While in Peru, Dr. Tatum lectured at the medical school.——Dr. M. G. Peterman, Milwaukee, has been elected state chairman of the American Academy of Pediatrics.

**Organize Public Health Association.**—Formal organization of the Wisconsin Association for Public Health took place December 21 in Madison. Among the officers elected were Dr. William D. Stovall, State Board of Health, Madison, president, and Bruce Dimmit, Green Bay sanitary engineer, secretary-treasurer. The association will differ from the Wisconsin Public Health Council in that the dominant membership will be professional workers in the field rather than lay members.

**The Carey Lecture.**—Dr. Helen B. Taussig, Baltimore, will be the guest speaker at the second annual Eben J. Carey Memorial lectureship February 9 at 4 p. m. in the Marquette University School of Medicine Auditorium in Milwaukee. After the lecture a dinner will be held in Dr. Taussig's honor. The lecture is sponsored by the Alpha Lambda chapter of Phi Delta Epsilon fraternity in honor of the late dean of Marquette University School of Medicine.

## WYOMING

**Tuberculosis Registry.**—The Central Tuberculosis Registry of the Wyoming State Department of Public Health began operating January 1. The registry will aid in getting information back to physicians in the state and serve as a means of keeping accurate statistics on tuberculosis. Further information may be obtained from the Tuberculosis Control Division, Cheyenne.

## ALASKA

**Eskimos Given BCG Vaccine.**—Vaccinations for the control of tuberculosis have been completed at Point Barrow, Alaska, where 600 Eskimos was examined and 250 received antituberculosis vaccine from a physician attached to the Bureau of Indian Affairs, according to the *New York Times.* Similar work has been conducted in Southeastern Alaska, Sitka and Wrangell.

## HAWAII

**Panel on Pneumatology.**—The Society for the Prevention of Asphyxial Death, Inc., conducted a panel on pneumatology at the Mabel Smyth Auditorium, Honolulu, T. H., January 11. Cooperating agencies were the medical corps of the U. S. Army and Navy, and the U. S. Public Health Service. Dr. Maurice L. Brodsky, U. S. Public Health Service, Honolulu, spoke on "The Asphyxial Hazard in Tuberculosis and in Other Respiratory and Circulatory Conditions," and Commander Walter Welham of the Pacific Fleet spoke on "Submersion in the Navy During World War II." The second part of the program was devoted to resuscitation, with Colonel Harold H. Twitchell of the Tripler General Hospital, Honolulu, and Paluel J. Flagg as the speakers.

## GENERAL

**Change Date of Surgical Congress.**—The dates for the Southeastern Surgical Congress have been changed from January 24-27 to May 23-26, according to the secretary, Dr. Benjamin T. Beasley.

**Create Board of Thoracic Surgery.**—The Board of Thoracic Surgery was established as an affiliate of the American Board of Surgery, Inc., on Oct. 2, 1948 at a meeting in Detroit. Information regarding the requirements of this board may be obtained by writing William M. Tuttle, M.D., secretary-treasurer, 1151 Taylor Avenue, Detroit 2.

**Panamerican Medico-Social Congress.**—The Panamerican Medico-Social Congress, postponed from December 3-10, will be held in Lima, Peru, February 20-26. For the program agenda see The Journal, Oct. 23, 1948, page 603. Those planning to attend may obtain information from Gilberto Morey Sotomayor, Secretary, Second Panamerican Medico-Social Congress, Asociacion Medica Peruana Villalta 218, Apartado 926, Lima, Peru.

**Society Election.**—The Society of American Bacteriologists selected the following officers for 1949: Dr. William McD. Hammon, San Francisco, president, and Dr. John E. Blair, New York, secretary-treasurer. The annual meeting of the society will be held May 16-20 in Cincinnati.——The American Academy of Dermatology and Syphilology, meeting in Chicago in December, chose Dr. Francis E. Senear, Chicago, as president and Dr. Louis A. Brunsting, Rochester, Minn., as secretary.

**Health Check-Ups in Industry.**—A survey recently released by the National Industrial Conference Board, shows that 16.5 per cent of the 333 establishments surveyed require that executives undergo periodic physical examination. Medical directors were found in more than 50 per cent and assistant medical directors in 13.5 per cent of the companies. Dentists are found in 41 organizations, x-ray technicians in 50 companies, medical laboratory technicians in 46 and physical therapists in 22. Eighty-three companies employ first-aid attendants and 20, practical nurses.

**Color Film on Cancer.**—A color motion picture, "Cancer: The Problem of Early Diagnosis," designed to educate the general practitioner in the treatment of cancer, has been produced jointly by the American Cancer Society and the National Cancer Institute. Five other half hour films, each dealing with a specific site of cancer, will be offered during the next two years to doctors throughout the country. Actual operations are followed by cameras placed directly over the surgeons' hands: Family physicians are shown examining patients in their own offices; charts indicate the course of metastasis of unchecked cancer. In regard to availability of the film, see Motion Picture Review in this issue, page 328.

**Awards in Endocrinology.**—The Association for the Study of Internal Secretions will give three awards for meritorious work in endocrinology at its annual meeting June 3-4 in Atlantic City, N. J. A committee of five members will choose recipients nominated by members of the association. All nominations, accompanied by a statement of the importance of the nominee's contribution to endocrinology and a bibliography of his most important papers, should be sent to the secretary, Dr. Henry H. Turner, 1200 North Walker Street, Oklahoma City 3 not later than March 15. The awards are the E. R. Squibb and Sons Award of $1,000, the Ciba Award of $1,200 and the Ayerst, McKenna and Harrison Fellowship.

**Meeting on Blindness.**—The National Society for the Prevention of Blindness will hold a three day national conference March 16-18 at the Hotel New Yorker in New York. The theme of the meeting will be "The Battle Against Blindness—the Next 40 Years," and the following subjects will be discussed: eye problems in middle life, the eyes of children and young adults, vision in industry, medical advances in sight conservation and glaucoma—a community problem. Persons directly or indirectly concerned with eye health and safety will find this conference of interest. Details may be obtained by writing to the society at 1790 Broadway, New York 19.

**Communicable Diseases.**—The U. S. Public Health Service reports that, for the week ending January 1, 1 case of smallpox was reported in each of the following states: North Dakota, South Dakota, Nebraska and Montana; 1 case of anthrax was reported in California; 1 case of Rocky Mountain spotted fever in Georgia, and 46 cases of tularemia in the country as a whole. The cumulative figures for fifty-two weeks ending January 1 indicate that the incidence of poliomyelitis during the recent epidemic was higher in South Dakota than in any other state, followed in order by North Carolina, Nebraska, California, Minnesota and Iowa. The number of cases of influenza reported by state health officers for the week ending January 1 was not unusually high in any part of the country. The reported incidence of scarlet fever remained low, although the total number of cases for the week (1,935) was higher than the number for the corresponding week of the previous year (1,668); however, it was below the median figure for the previous five years (2,211).

**National Cancer Conference.**—The first annual National Cancer Conference, sponsored jointly by the American Cancer Society and the National Cancer Institute of the U. S. Public Health Service, will be held at the Hotel Peabody, Memphis, Tenn., February 25-27. The program will open with a discussion of fundamental biologic problems of growth with Clarence C. Little, Sc.D., Bar Harbor, Me., acting as moderator. The program up to the Friday afternoon session is made up of round table discussions of cancer according to site, type and frequency, and administration of grants, professional education technics and cancer services and facilities. At the general meeting Friday afternoon summaries of panel discussions will be presented by the moderators of each panel, and Dr. Morris K. Barrett, National Advisory Cancer Council, Bethesda, Md., will give a summary of the Proceedings of the National Gastric Conference in San Francisco, December 13-14. All sessions will be open to physicians who may desire to audit the proceedings.

**WHO to Administer International Prizes.**—The assets of the Léon Bernard Foundation, which periodically awards an international prize for practical results obtained in social medicine, have been turned over to the World Health Organization to be administered by the director-general. Selection of the recipient of the prize will be among the duties of the Expert Committee on Social Medicine, which is to be appointed by the Health Assembly. The International Malariology Prize awarded by the Darling Foundation to the author of an original study on the pathology or prophylaxis of malaria will henceforth be administered by the World Health Organization. The Expert Committee on Malaria will recommend a candidate for the medal and prize. The Léon Bernard Foundation was established in 1937 by international subscription to perpetuate the memory of Professor Léon Bernard, a member of the Health Committee of the League of Nations. The Darling Foundation was created by prize funds in 1945 in memory of Dr. S. T. Darling, who was accidentally killed during a study mission of the League of Nations Malaria Commission.

**Yale Summer School of Alcohol Studies.**—The summer school of Alcohol Studies, conducted annually since 1943 by the Laboratory of Applied Physiology of Yale University, will hold two separate but equivalent sessions this year. A Western session will be held from June 6-29 on the campus of Trinity University at San Antonio, Texas, and an Eastern session will be held at Yale University in New Haven, Conn., July 8 to August 5. The curriculum, consisting of lectures, seminars and demonstrations, deals with the medical, psychologic, physiologic, psychiatric, sociologic, economic, legal, religious, educational and therapeutic aspects of alcohol problems. During the second half of each session the curriculum is divided into two parts for the professional groups concerned particularly with the educational or the therapeutic aspects of alcoholism. The summer school is under the directorship of Elvin M. Jellinek, Sc.D. The lecturers, mainly from the faculties of Yale University and Texas Christian University, Fort Worth, include authorities who have done original research in their fields as well as representatives of other national institutions of education, research, treatment or rehabilitation. Applications for admission to the Western session will be received up to April 1 and for the Eastern session up to April 15. Application blanks for either session may be obtained by writing to the executive Secretary, Summer School of Alcohol Studies, Yale University, New Haven, Conn.

**Review of Soviet Medicine Suspends Publication.**—The *American Review of Soviet Medicine*, which has served during the last five years to link medical workers in Soviet Russia with others in the world, has suspended publication. The announcement was made in an editorial by Dr. Henry E. Sigerist, consultant editor of the *Review*. Dr. Sigerist said, "For five years we have endeavored to establish an exchange of medical information in a free spirit between two great countries . . . . We did the best we could during and after the war under continuously difficult circumstances. Much to our regret we are unable to [carry on the publication of the *Review*] for reasons which are so obvious we need not elaborate on them." The American-Soviet Medical Society, publisher of the *Review*, will "carry on and will continue to keep its members informed about medical developments in the U.S.S.R. by issuing mimeographed reports whenever there is an opportunity." Dr. Sigerist says that the society library will continue to function at the New York Academy of Medicine and that it is hoped the society will some day be able to resume its full program of activities, including the publication of the *Review*. The *Review's* board of editors included such physicians as Drs Leo M. Davidoff, New York; John F. Fulton, New Haven; Bela Schick, New York; Stuart Mudd, Haverford, Pa.; Abraham Stone, New York; Joseph Wortis, New York; Jacob Heiman, New York, and Selman A. Waksman, Ph.D., Clifton, N. J.

**Rheumatic Fever Council.**—At the meeting of the American Council on Rheumatic Fever December 3 in New York City, the following officers were elected for 1949: Dr. Rustin McIntosh, New York, chairman; Mr. Lawrence Linck, Chicago, vice chairman; Dr. Ann G. Kuttner, New York, secretary, and Dr. George M. Wheatley, New York, treasurer. The council, which is part of the American Heart Association, appointed the following committees and chairmen: Research Study Committee, Dr. Kuttner; Committee on Community Rheumatic Fever Programs, Dr. Wheatley; Committee on Standards and Criteria for Rheumatic Fever and Rheumatic Heart Disease, Dr. David D. Rutstein, New York; Membership Regulations Committee, Dr. Harold M. Marvin, New Haven, Conn., and Committee on Education and Training, chairman to be appointed. The American Council on Rheumatic Fever was created in 1944 to correlate the interests of various voluntary health organizations concerned with rheumatic fever and rheumatic heart disease and to coordinate these efforts with similar activities in the government field. The council was established under the certificate of incorporation of the American Heart Association, and there is interlocking membership in the governing bodies of the council and the association. The organizations belonging to the council include: American Academy of Pediatrics, American Association of Medical Social Workers, American College of Physicians, American Heart Association, American Hospital Association, American Medical Association, American Nurses Association, American Public Health Association, American Rheumatism Association, American School Health Association, National Organization for Public Health Nursing and National Society for Crippled Children and Adults.

## FOREIGN

**Medical Society of Aix-les-Bains.**—The meeting of the Medical Society of Aix-les-Bains to be held May 29 will be concerned chiefly with the study of ankylosing spondylarthritis to be presented by Dr. J. Forestier. For further information address Dr. G. du Lac, general secretary of the Medical Society, Rue de Liege, Aix-les-Bains, France.

**Festival to Commemorate Science and Art of Healing.**—The opening service of the Canterbury Festival of 1949 on June 25 will be the Commemoration of the Science and Art of Healing. Doctors and scientists from the United States who are in England are invited to attend. The commemoration service will include the medical and nursing professions and also organizations concerned with medical science and research. The Festival is held each year in Canterbury and a special service of a commemorative nature is planned for its opening.

**Medical School Destroyed by Fire.**—The School of Medicine of the University of Chile was recently virtually destroyed by fire. The library of the school, comprising 50,000 volumes, of which about 40 per cent was saved, had just been reorganized by Edward Heiliger of the Rockefeller Foundation after two years' work. The journals published before 1940 and 40 per cent of those published after 1939 were saved. The extensive bibliographic material in the Institute of Biology and in the Institute of Microbiology was destroyed. The U. S. Army Medical Library is planning to supply from duplicate stocks some of the books and journals needed in the reconstruction of the Chilean collections.

**International Congress of Biochemistry.**—The first International Congress of Biochemistry is to be held in Cambridge, England, August 19-25. The congress is being organized in eleven sections for reading of papers and for discussions on Animal Nutrition and General Metabolism, Microbiological Chemistry, Enzymes and Tissue Metabolism, Proteins, Clinical Biochemistry, Structure and Synthesis of Biologically Important Substances, Cytochemistry, Biological Pigments, Hormones and Steroids, Chemotherapy and Immunochemistry, and Plant Biochemistry. There will also be congress lectures and visits to research institutes and laboratories. The fee is 2 pounds sterling, to be sent to Francis J. Griffin, honorary organizer, 56 Victoria Street, London, S.W.1.

**Cyprus to Wipe Out Malaria.**—After a two year battle to wipe out malaria the Island of Cyprus is nearly free of the disease, according to the *New York Times*. In 1945 40 per cent of all school children suffered from malaria; in 1948 the rate had been reduced to 1.3 per cent. Only 3 new cases were discovered during 1948. The Cyprus health authorities sprayed the entire island and incoming aircraft with DDT (dichloro-diphenyltrichloroethane) at a total cost to date equivalent to $800,000. The island was divided into squares of 3 to 8 square miles, and a weekly report is turned in on every small square. Its topography is so difficult that men have had to be lowered over cliffs to get at some streams and pools; other pools could be reached only by small boats along the coast. Every infant has his blood examined periodically for malaria parasites, as do all school children. The entire campaign is expected to be completed in 1949 well within the original budget of $1,200,000.

## Deaths in Foreign Countries

**Dr. Karl Bonhoeffer**, who was professor of psychiatry at Berlin University from 1912 to 1938, died in Berlin December 4, aged 80. Last May he was made an honorary member of the American Psychiatric Association.

## CORRECTION

**Inter-American Congress on Brucellosis.**—The title of the paper presented by Dr. Leo Lowbeer of Tulsa, Okla., before the Inter-American Congress on Brucellosis at the meeting in Buenos Aires in November was "Pathology of Brucellotic Osteomyelitis in Man and Animal" and not "The Pathology of Swine Brucellosis," as stated in The Journal, January 15, page 167.

# Marriages

William Otis Bailey Jr., Washington, D. C., to Miss Frances Claire Wisnewski of Kingston, Pa., in South Hadley, Mass., December 17.

Arthur D. Wolk, Rutland, Vt., to Miss Florence E. Schwartzberg of Woodmere, L. I., N. Y., November 25.

John Richard Sosnowski, Charleston, S. C., to Miss Elizabeth Wright Tyson in Baltimore, December 11.

James Slater Murphy, New York, to Miss Margaretta Large Fitler of Philadelphia, December 11.

George F. Parton Jr., Bronxville, N. Y., to Miss Phyllis Burdett in Swampscott, Mass., November 27.

Lawrence Stanley Bodziner, New Orleans, to Miss Dena Yaschik of Charleston, S. C., November 14.

Richard Howe Hart, Chicago, to Miss Louise Ann Threlkeld of Maplewood, N. J., November 26.

Harold Redd Jr., Lexington, Ky., to Miss Phyllis Virginia Anderson at Oglesby, Ill., November 16.

Kenneth Robert Niswander to Miss Marjorie Ruth Fowler, both of Buffalo, December 20.

Gemma Margaret Lichtenstein to Mr. Homer Rigdon Rizner, both of Chicago, December 10.

Wilson Greene Jr., Sumter, S. C., to Miss Anne Porcher Gregorie of Charleston, December 18.

Hurst Bunn Hatch, Raleigh, N. C., to Miss Frances Gail Buchtel in New Orleans, December 3.

Erwin Oskar Hirsch, Boston, to Miss Emily Grant Stanley in Orange, N. J., November 27.

James Francis Morrell to Miss Joan Marie Vaughan, both of Brooklyn, November 13.

Arthur Miller, Brooklyn, to Miss Hope Ruth Simon of New York, December 5.

# Deaths

**Arthur Many Johnson**, Rochester, N. Y.; born in Binghamton, N. Y., Nov. 4, 1874; Albany (N. Y.) Medical College, 1895; member of the American Medical Association and of the American Public Health Association; coroner's physician from 1902 to 1904; part time health physician from 1905 to 1921 and deputy health officer from 1921 to 1925, when he became full time deputy health officer; health officer from 1932 to 1945; served during World War I; part time lecturer in medicine (public health) at the University of Rochester School of Medicine and Dentistry, where he was consultant in public health from 1932 to 1938; in 1943 the Rochester Academy of Medicine presented him its highest award, the Albert D. Kaiser Medal, for "outstanding service to the medical profession"; member of the board of visitors of the Rochester State Hospital; on the consulting staff of Strong Memorial Hospital, where he died November 30, aged 74, of carcinoma of the lung.

**Herbert Charles Gibner** ⊕ Colonel, U. S. Army, retired, San Francisco; born in Bridgeport, Conn., Oct. 9, 1879; Yale University School of Medicine, New Haven, 1903; Army Medical School, 1905; Army War College, 1924; fellow of the American College of Surgeons; entered the medical corps of the U. S. Army as a first lieutenant in 1905; promoted through the various ranks to that of colonel; served during World War I; retired Jan. 13, 1943; formerly commandant of the Army Specialized Training Unit of the University of California Medical School and commandant of the U. S. Army Medical Field Service School at Carlisle, Pa.; in 1945 received the Legion of Merit for outstanding service while Seventh Service Command surgeon; died in the Letterman General Hospital, November 13, aged 69, of carcinoma of the ampulla of Vater with generalized carcinomatosis.

**Earl Kendall Holt**, Medfield, Mass.; Indiana University School of Medicine, Indianapolis, 1914; member of the American Medical Association, American Psychiatric Association and New England Society of Psychiatry; specialist certified by the American Board of Psychiatry and Neurology, Inc.; formerly director of the division for the examination of prisoners in the department of mental diseases; served in various capacities while assigned to the Veterans Bureau; at one time assistant superintendent of the Monson State Hospital in Palmer; consultant for the Norfolk County Hospital, Braintree; for many years superintendent of the Medfield State Hospital; died November 10, aged 59, of coronary occlusion.

**Courtland Prentice Gray Sr.** ⊕ Monroe, La.; born in Pelahatchie, Miss., in 1882; Maryland Medical College, Baltimore, 1904; past president of the Louisiana State Medical Society, Fifth District Medical Society and the Quachita Parish Medical Society; formerly councilor of the Fifth District of the Louisiana State Medical Society; for many years coroner of Quachita Parish; examiner of the local draft board during World War I; member of the board of appeals, Selective Service, during World War II; on the staff of St. Francis Sanitarium; superintendent of the Conway Memorial Hospital; died November 20, aged 66, of cerebral hemorrhage.

**Holland McTyeire Tigert** ⊕ Nashville, Tenn.; University of Nashville Medical Department, 1901; past president of the Tennessee State Medical Association, Nashville Academy of Medicine and the Davidson County Medical Society; member of the Southern Surgical Association; fellow of the American College of Surgeons; served overseas during World War I; associate professor of clinical gynecology at the Vanderbilt University School of Medicine; member of the surgical staff, Vanderbilt, St. Thomas and Nashville General hospitals; died in the Veterans Administration Hospital November 14, aged 68.

**Edward J. Tracey** ⊕ Norwalk, Conn.; University of Pennsylvania School of Medicine, Philadelphia, 1924; certified by the National Board of Medical Examiners; fellow of the American College of Surgeons; for many years physician to the city fire department; served on the faculty of Columbia University College of Physicians and Surgeons in New York; on the staff of the Norwalk General Hospital; affiliated with the New York Post-Graduate Medical School and Hospital in New York, where he died November 17, aged 48, of Laennec's cirrhosis of the liver.

**Abner Osburn Albin**, Charles Town, W. Va.; College of Physicians and Surgeons, Baltimore, 1903; died November 15, aged 72, of carcinoma.

**Thomas Edward Bailly**, San Francisco; Cooper Medical College, San Francisco, 1892; member of the American Medical Association; fellow of the American College of Surgeons; for many years affiliated with St. Mary's Hospital, where he died November 15, aged 79, of arteriosclerosis.

**Leonard Allen Baker** ⊕ Miami, Fla.; University of Georgia Medical Department, Augusta, 1908; affiliated with Jackson Memorial Hospital; died November 5, aged 66, of uremia.

**Raymond DeWight Baker** ⊕ Summit, N. J.; University and Bellevue Hospital Medical College, New York, 1899; served during World War I; affiliated with Overlook Hospital; died in Lumberton, N. C., November 3, aged 70, of injuries received in an automobile accident.

**Hendrick Nelson Belgum**, Richmond, Calif.; Rush Medical College, Chicago, 1911; died November 8, aged 64, presumably of a coronary attack while fighting a brush fire.

**John Robert Belk**, Kershaw, S. C.; Medical College of the State of South Carolina, Charleston, 1913; died in the Camden (S. C.) Hospital November 19, aged 70, of heart disease.

**George B. Beresford**, Owensville, Ind.; Indiana Eclectic Medical College, Indianapolis, 1887; member of the American Medical Association; died November 5, aged 85, of uremia.

**Don Bertus Biggs**, Findlay, Ohio; Starling Medical College, Columbus, 1902; member of the American Medical Association; formerly county coroner; affiliated with the Findlay Hospital; died recently, aged 75, of coronary thrombosis.

**Roy Henry Blender**, Seattle; University of Arkansas School of Medicine, Little Rock, 1938; died November 6, aged 37, of uremia.

**Louisa Elizabeth Boutelle**, Cherokee, Iowa; University of Minnesota Medical School, Minneapolis, 1916; member of the American Medical Association, Utah State Medical Association and the New England Society of Psychiatry; certified by the National Board of Medical Examiners; affiliated with Cherokee State Hospital; died November 3, aged 62, of coronary occlusion.

**William Hollis Bradford** ⊕ Chevy Chase, Md.; University of Cincinnati College of Medicine, 1928; member of the Florida Medical Association; assistant chief of surgical service at the central office of Veterans Administration in Washington, D. C.; served as chief medical officer and manager of the Veterans Administration Hospital in Brecksville and on the staffs of various other Veterans Administration hospitals; died in the Crile Veterans Administration Hospital in Cleveland, November 15, aged 47, of carcinoma of the rectum.

**Arthur Scott Bronson**, San Antonio, Texas; Homeopathic Medical College of Missouri, St. Louis, 1901; member of the American Medical Association; specialist certified by the American Board of Otolaryngology; a charter member and past president of the San Antonio Eye, Ear, Nose and Throat Society; on the staffs of the Robert B. Green Hospital, Santa Rosa Hospital and Medical and Surgical Memorial Hospital; died recently, aged 69, of heart disease.

**Ethel Doty Brown** ⊕ New York; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1890; served as trustee of the New York Infirmary; died in the New York Hospital November 8, aged 80.

**Frank Louis Brown** ⊕ Chicago; Chicago College of Medicine and Surgery, 1912; fellow of the American College of Surgeons; in 1931 member of the House of Delegates of the American Medical Association; on the staff of the Garfield Park Community Hospital; died December 7, aged 62, of carcinoma of the liver.

**George Byron Brown**, Clarion, Iowa; John A. Creighton Medical College, Omaha, 1915; member of the American Medical Association; served during World War I; formerly mayor of Clarion and county coroner; died recently, aged 66, of cerebral hemorrhage and hypertension.

**Theodore David Burger**, Spokane, Wash.; University of Illinois College of Medicine, Chicago, 1913; member of the American Medical Association; served on the school board; on the staff of the Deaconess Hospital; died recently, aged 61.

**Bruce Fowler Butler**, Hollywood, Fla.; University College of Medicine, Richmond, 1911; member of the American Medical Association; died in the Duke Hospital, Durham, N. C., November 14, aged 61.

**Arthur M. Butzow** ⊕ Chicago; Rush Medical College, Chicago, 1898; on the staff of the Swedish Covenant Hospital, where he died November 21, aged 74, of coronary thrombosis.

**Edwin Alga Cameron** ⊕ East Orange, N. J.; University of Vermont College of Medicine, Burlington, 1915; served during World War I; affiliated with the Orange, N. J., Memorial Hospital; died November 17, aged 57, of coronary occlusion.

**Matthew Elmer Campbell,** Abilene, Texas; Barnes Medical College, St. Louis, 1899; member of the American Medical Association; died October 15, aged 80, of arteriosclerosis.

**Walton Gardner Card** ⊕ Haverhill, Mass.; Tufts College Medical School, Boston, 1925; on the staff of Hale Hospital; died November 11, aged 59, of heart disease.

**James Gilbert Carney,** San Francisco; University of Illinois College of Medicine, Chicago, 1914; served in France during World War I; formerly affiliated with the Veterans Administration; died November 9, aged 67.

**Starr King Church,** Marshall, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892; member of the American Medical Association; past president of the Calhoun County Medical Society; served as a member of the city council, county coroner, health officer and secretary of the school board; for many years secretary-treasurer of the Rotary Club and physician for the New York Central Railroad; affiliated with the Oaklawn Hospital, where he died November 19, aged 81, of carcinoma of the bladder.

**David Wesley Clark,** Vega, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1891; member of the American Medical Association; past president of the Randall-Deaf Smith-Parmer-Castro-Oldham Counties Medical Society; served as secretary of the Montague County Medical Society; for many years health officer of Montague County and Oldham County; died October 5, aged 79, of cerebral hemorrhage.

**Henry F. Clay,** Henderson, Ky.; University of Louisville (Ky.) Medical Department, 1898; member of the American Medical Association; died in St. Anthony's Hospital, Rock Island, Ill., November 5, aged 76.

**Grover Cleveland Coleman** ⊕ Birmingham, Ala.; University of Alabama School of Medicine, 1911; for many years associated with the Tennessee Coal, Iron and Railroad Company; died in Panama City, Fla., November 15, aged 64, of coronary occlusion.

**Harry Samuel Conrad** ⊕ St. Joseph, Mo.; Ensworth (Mo.) Medical College, St. Joseph, 1913; past president of the Buchanan County Medical Society; died November 20, aged 62.

**George Holden Coombs** ⊕ Waldoboro, Me.; University of the City of New York Medical Department, New York, 1886; formerly director of the state bureau of health; past president of the Maine Medical Association and of the Knox County Medical Society; affiliated with Knox County General Hospital, Rockland, and Miles Memorial Hospital in Damariscotta, where he died November 20, aged 85, of intracranial hemorrhage.

**John Robert Crawford,** Blue Springs, Mo.; Marion-Sims College of Medicine, St. Louis, 1893; died in the Veterans Administration Hospital, Wadsworth, Kan., October 20, aged 79, of arteriosclerotic heart disease and amputation of a right extremity.

**William Eugene Currier,** Leominster, Mass.; Harvard Medical School, Boston, 1898; member of the American Medical Association; a retired school physician; affiliated with the Leominster Hospital; died November 23, aged 77, of coronary thrombosis.

**Elbert Austin Curtis** ⊕ Newark, N. J.; Marion-Sims College of Medicine, St. Louis, 1896; served during World War I; on the staffs of City Hospital, Presbyterian Hospital and Hospital of St. Barnabas for Women and Children; died December 2, aged 75.

**Ella Buchanan Custer,** Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1883; member of the American Medical Association; recipient of the Citizenship Award as the outstanding citizen of the twenty-first ward during 1934; died November 8, aged 87, of coronary occlusion.

**Mardiros Hovhannes Derian** ⊕ Gary, Ind.; Loyola University School of Medicine, Chicago, 1918; affiliated with Methodist and St. Mary's Mercy hospitals; died in Chicago Memorial Hospital November 1, aged 61, of pulmonary embolus and purulent pericarditis.

**Frank Henry Dillon,** Colchester, Ill.; St. Louis College of Physicians and Surgeons, 1909; died in St. Francis Hospital, Macomb, November 6, aged 63.

**David Ernest Dolloff** ⊕ Biddeford, Me.; Medical School of Maine, Portland, 1907; served overseas during World War I; affiliated with the Trull and Webber hospitals; died November 26, aged 70, of cerebral embolism.

**LeRoy Edson Doolittle** ⊕ Duluth, Minn.; University of Minnesota Medical School, Minneapolis, 1909; served during World War I; affiliated with St. Luke's Hospital and St. Mary's Hospital, where he died November 9, aged 65, of coronary occlusion and hypertension.

**William Tovey Drysdale,** Boise, Idaho; Denver and Gross College of Medicine, 1903; served during World War I; specialist certified by the American Board of Psychiatry and Neurology, Inc.; member of the American Psychiatric Association; served on the staffs of Veterans Administration hospitals at various places; on the staff of the Veterans Administration Hospital in Boise, where he died November 16, aged 66, of cerebral thrombosis.

**John Dugan** ⊕ Albion, N. Y.; University of Buffalo School of Medicine, 1896; an Associate Fellow of the American Medical Association; served as health officer; medical examiner for the county draft board during World Wars I and II; died in Rochester, November 12, aged 77, of coronary heart disease.

**John P. Du Pre,** Fountain Inn, S. C.; Medical College of the State of South Carolina, Charleston, 1903; died in the Greenville (S. C.) General Hospital November 15, aged 76, of hypertrophic arthritis and melanoma.

**Henry Wyley Giles,** Aledo, Ill.; Keokuk (Ia.) Medical College, 1895; died in Geneseo, November 6, aged 87.

**Frank Henry Gordon,** Los Angeles; Rush Medical College, Chicago, 1891; died November 1, aged 82, of pneumonia.

**Kurt Max Grassheim** ⊕ New York; Johann Wolfgang Goethe-Universität Medizinische Fakultät, Frankfurt-am-Main, Prussia, 1921; died in the Harkness Pavilion of the Columbia Presbyterian Medical Center November 15, aged 51.

**Wilmer Eli Griffith,** Columbus, Ohio; Columbian University Medical Department, Washington, D. C., 1900; once health commissioner of Hamilton, where he was on the staffs of the Mercy and Fort Hamilton hospitals; died in Bridgeville, Pa., recently, aged 80, of arteriosclerosis.

**Francis E. Griswold,** Hoffman, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1897; member of the American Medical Association; served on the staff of Our Lady of Mercy Hospital, Alexandria; died in Minneapolis November 1, aged 74, of carcinoma.

**John Henry Hallock,** Saranac Lake, N. Y.; New York Homeopathic Medical College, New York, 1886; died November 3, aged 90.

**Eugene Paul Hamilton,** Richmond, Mo.; St. Louis University School of Medicine, 1908; member of the American Medical Association; formerly practiced in Kansas City, where he was on the staffs of the Kansas City General, St. Joseph and St. Mary's hospitals; died November 1, aged 68, of coronary occlusion.

**George Johnson Hamilton,** New York; L. R. C. P. and M. R. C. S., London, 1934; council of the American Proctologic Society; served in the European theater during World War II; on the staff of the Polyclinic Hospital; died November 12, aged 47.

**John Cyril Hewgill,** Akron, Ohio; University of Toronto Faculty of Medicine, London, Ontario, Canada, 1922; served during World Wars I and II; died suddenly, November 8, aged 50.

**John Levoy Higbie,** Jenera, Ohio; Missouri Medical College, St. Louis, 1888; served as president of the Jenera Bank, mayor of the village and on the board of education; died in Sawyer Sanatorium, Marion, November 12, aged 85, of arteriosclerotic heart disease.

**Thomas Yue Ho** ⊕ St. Johns, Mich.; Northwestern University Medical School, Chicago, 1923; member of the American Society of Anesthetists and the Radiological Society of North America; for many years secretary-treasurer of the Clinton County Medical Society; affiliated with Clinton Memorial Hospital; died November 19, aged 51, of heart disease.

**Edgar Rea Holmes,** Minier, Ill.; College of Physicians and Surgeons of Chicago, 1887; member of the American Medical Association; died in Mennonite Hospital, Bloomington, November 16, aged 84.

**Joel Dubois Holston** ⊕ Massillon, Ohio; Eclectic Medical Institute, Cincinnati, 1896; member of the Radiological Society of North America, Inc., and the American College of Radiology; specialist certified by the American Board of Radiology; served during World War I; formerly member of the board of education; on the staff of the Massillon City Hospital; died in the University Hospital, Cleveland, recently, aged 80, of sarcoma of the adrenal glands.

**Rinaldo M. Hughey,** Washington C. H., Ohio; Columbus Medical College, 1891; member of the American Medical Association; for many years president of the school board; for two terms member of the state legislature, serving as county representative; died recently, aged 81, of chronic myocarditis.

**Annie M. Hull,** Glens Falls, N. Y.; New York Medical College for Women, New York, 1903; member of the American Medical Association; died November 22, aged 70.

**Richard Cooke Johnston,** Spokane, Wash.; University of Pennsylvania School of Medicine, Philadelphia, 1937; member of the American Medical Association; awarded the Bronze Star for meritorious service with the Marines on Peleliu Island during World War II; died November 15, aged 36, of coronary occlusion.

**Richard F. King,** Jamestown, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1881; died recently, aged 93, of cardiovascular renal disease.

**Mark Stevens Knapp,** Fenton, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1898; member of the American Medical Association; fellow of the American College of Physicians; first executive secretary and director of medical research, Horace H. and Mark A. Rackham Fund; formerly practiced in Flint, where he was president of the Genesee County Medical Society, health officer, and on the staffs of the Hurley and Women's hospitals; died November 11, aged 76.

**Morton Paul Lane,** New York; Tulane University of Louisiana School of Medicine, New Orleans, 1914; served during World War I; died in the Veterans Administration Hospital November 5, aged 58.

**Robert Hood Lister,** Ozark, Ala.; University of Alabama School of Medicine in University, 1916; served during World War I; died November 7, aged 62, of heart disease.

**George Munro Livingston** ⊕ Albion, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1898; for many years associated with the Highland Park (Mich.) General Hospital; died in Sheldon Memorial Hospital, November 1, aged 81, of cerebral hemorrhage.

**William Sumner McCausland,** Chula Vista, Calif.; Western Pennsylvania Medical College, Pittsburgh, 1904; member of the American Medical Association; served as chief of staff of Chula Vista Hospital; died November 7, aged 70, of adenocarcinoma of the stomach.

**William C. McClain,** Knoxville, Tenn.; Lincoln Memorial University Medical Department, Knoxville, 1913; member of the American Medical Association; died in Fort Sanders Hospital November 1, aged 66, of agranulocytic neutropenia.

**Milton T. McDowell,** Maxwell, N. M.; Louisville (Ky.) Medical College, 1901; died October 9, aged 76, of coronary thrombosis.

**Noah C. McLean,** Enid, Okla.; Barnes Medical College, St. Louis, 1899; died in a hospital at Wichita, Kan., recently, aged 78, of carcinoma of the prostate.

**William John McNerney** ⊕ Syracuse, N. Y.; Syracuse University College of Medicine, 1912; clinical professor emeritus of medicine at his alma mater; affiliated with the Hospital of Good Shepherd; died November 17, aged 64, of heart disease.

**Jesse Lynn Mahaffey** ⊕ Camden, N. J.; Medico-Chirurgical College of Philadelphia, 1902; past president of the Conference of State and Provincial Health Authorities and of the Camden County Medical Society; for many years director of the state board of health; served on the staff of Cooper Hospital; died November 1, aged 69.

**Edwin J. Meyer** ⊕ Chicago; Chicago College of Medicine and Surgery, 1913; formerly on the faculty of the Loyola University School of Medicine; for many years on the staff of St. George Hospital, where he died November 10, aged 65, of chronic interstitial nephritis.

**Bernard A. Michel** ⊕ Dubuque, Iowa; University of Pennsylvania Department of Medicine, Philadelphia, 1889; fellow of the American College of Surgeons; served on the staffs of Finley and St. Joseph's Mercy hospitals; died November 5, aged 88, of chronic myocarditis.

**Guy Miller,** Charlotteville, Va.; University of Virginia Department of Medicine, Charlottesville, 1888; also a pharmacist; died October 19, aged 79, of carcinoma.

**David Mathew Mitchel,** Brush, Colo.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1910; died in the Eben-Ezer Hospital, recently, aged 71.

**Eugene Poland Mitchell,** Defiance, Ohio; University of Louisville (Ky.) School of Medicine, 1923; member of the American Medical Association; formerly secretary treasurer of the Defiance County Medical Society; for many years city health commissioner; died in the Defiance Hospital recently aged 54, of carcinoma.

**Marshal Chalmers Morgan** ⊕ Akron, Ohio; Ohio State University College of Medicine, Columbus, 1913; died November 5, aged 61, of chronic nephritis with hypertension.

**Elmer J. Morrison,** Bar Harbor, Me.; College of Physicians and Surgeons, Baltimore, 1898; formerly member of the state legislature; served in the U. S. Navy during World War I; first medical examiner of Hancock County; died November 5, aged 86.

**Marjory M. Orr,** Belding, Mich.; Grand Rapids Medical College, 1902; died November 6, aged 74, of cerebral hemorrhage.

**Luther James Osgood** ⊕ Waukegan, Ill.; Northwestern University Medical School, Chicago, 1903; associate professor of medicine, emeritus, at his alma mater; died in the Lake Forest (Ill.) Hospital, November 6, aged 72, of carcinoma of the lung.

**Lewis Henry Pirkle,** Shreveport, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1904; member of the American Medical Association; fellow of the American College of Surgeons; medical examiner for the draft board during World Wars I and II; served as member and president of the parish school board; affiliated with Tri-State Sanitarium, of which he had been a founder, and Shreveport Charity Hospital; died in the North Louisiana Sanitarium November 5, aged 75, of heart disease.

**John Alexander Price,** Jasper, Tenn.; University of Tennessee Medical Department, Nashville, 1907; served during World War I; died November 10, aged 68, of cerebral hemorrhage.

**Lewis DeWitt Reed** ⊕ Hope, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1890; served as county health officer; for many years health officer of Hope; medical examiner and member of the advisory board during World War I; died October 16, aged 85, of carcinoma of the intestine.

**Burton William Rhuberry,** Detroit; Northwestern University Medical School, Chicago, 1943; served a residency at the Leland Sanatorium in Ypsilanti, Mich.; died in the Detroit Tuberculosis Sanatorium November 7, aged 34, of pulmonary tuberculosis.

**Edwin Albert Reisenfeld,** New York; University of Buffalo School of Medicine, 1903; served on the staffs of the Beth Israel Hospital and the Harlem Hospital; died in Cedars of Lebanon Hospital, Los Angeles, November 7, aged 67.

**Michael Davitt Riordan,** Willimantic, Conn.; University of Vermont College of Medicine, Burlington, 1912; member of the American Medical Association and the New England Obstetrical and Gynecological Society; health officer of the towns of Chaplin and Windham; affiliated with Windham Community Memorial Hospital; died October 28, aged 65, of myocardial infarction.

**Homer Lawrence Spaulding,** Ankeny, Iowa; Columbian University Medical Department, Washington, D. C., 1895; member of the American Medical Association; affiliated with Iowa Lutheran and Iowa Methodist hospitals; died October 23, aged 84, of bronchopneumonia.

**Romeo Roderick Stevenson,** Sioux Falls, S. D.; Northwestern University Medical School, Chicago, 1894; died October 25, aged 82, of cerebral embolus.

**William John Stewart,** Frankfort, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1909; member of the American Medical Association; president of the Marshall County Medical Society; served as county health officer and coroner; affiliated with Christ Hospital, Topeka, where he died October 21, aged 79, of coronary occlusion.

**Nathan Palmer Thompson,** St. Louis; Missouri Medical College, St. Louis, 1888; member of the American Medical Association; died October 31, aged 81.

**William E. Wheatley** ⊕ Lorain, Ohio; Western Reserve University Medical Department, Cleveland, 1894; served on the staff of St. Joseph's Hospital; fellow of the American College of Surgeons; recipient of the 1930 Achievement Award presented by the *Lorain Journal* to the town's most valuable citizen; died October 25, aged 77, of carcinoma of the pharynx.

**Bert George Wilcox** ⊕ Joliet, Ill.; Chicago College of Medicine and Surgery, 1912; fellow of the American College of Surgeons; member of the American Association of Industrial Physicians and Surgeons; affiliated with the Silver Cross and St. Joseph's hospitals; died in the Mayo Clinic, Rochester, Minn., November 3, aged 67, of carcinoma of the bladder.

**Samuel Rodford York** ⊕ Center, Ky.; University of Nashville (Tenn.) Medical Department, 1899; served as president of the Metcalf County Medical Society; on the staff of the T. J. Sampson Community Hospital, Glasgow; died October 29, aged 80, of coronary thrombosis.

### The Extravagance of the National Health Service

A characteristic of the socialist National Health Service, as of all other measures of the Government, is that it is costly and extravagant. This fact is illustrated by the following cases. Two partners set up practice in a small seaside town on June 1, 1948, only a few weeks before the coming into force of the service. They applied for the fixed annual payment of $1,200 which they said they had relied on, as the Ministry of Health had declared that new entrants to general practice would get a fixed annual payment for three years, and they could not continue practice without the payment. There were only 300 patients on their combined lists at the beginning of September. The local medical committee refused this request on the grounds that there were enough doctors in the area before the new practice was started and that the area could not provide a competence for two extra doctors. The doctors appealed to the Minister of Health against this decision, which he reversed on the following grounds: 1. The doctors had just started a new practice and would suffer hardships without the $1,200. 2. The number of doctors in the area is a factor to be taken into account in considering applications made after July 5 to be placed on the medical list but ought not to affect the granting of the $1,200. But the conditions were laid down that within a period to be specified by the Distribution Scheme (when available) the doctors have on their lists the minimum number of patients specified by that scheme.

A similar appeal was made in the case of a doctor practicing in another small seaside town, who took a younger man into partnership a short time before the service came into force. Both doctors applied for the $1,200 a year. The local medical committee refused on the grounds that the practice was originally a one doctor practice, the younger doctor could be regarded as undergoing a period of introduction with view to succession and there was no question of hardship if the practice was so regarded. But the Minister again reversed the local decision. The *British Medical Journal* regards as remarkable that a Minister who introduced elaborate machinery to secure a reasonable distribution of doctors should "subsidize practitioners at the public expense—and at the expense of other practitioners in the area—to practice in an area where they are not needed."

Extravagance as regards materials has been mentioned in previous letters to THE JOURNAL, such as the case of the woman who evidently had no need for the free medicine which had been prescribed for her under the National Health Service, and obtained, with the connivance of the pharmacist, free cosmetics instead. The waste of the taxpayer's money in other directions is becoming more evident, Dr. G. H. Harvey writes to the *British Medical Journal* that he is amazed by the extras, such as douches, nozzles, eye baths, pessaries, etc., which he is invited to supply. The strange and alarming fact is that the patients think that they get all these extras free because a benevolent government supplies them. He is convinced that the huge cost of prescribing now piling up will soon return to the public for payment by increased taxation.

In another letter to the *British Medical Journal* he relates what happens to some of the articles which have been supplied free. In the pawnshops of the town he found a considerable number of brand new spectacles. The rush for free spectacles has been mentioned in a previous letter to THE JOURNAL.

### Beryllium Poisoning

What appears to be the first death in this country from beryllium poisoning has been the subject of a coroner's inquest. The deceased was a physicist, aged 36 years, who had worked between December 1941 and December 1942 on the development of tubular fluorescent lamps. He handled about 500 tubes coated internally with phosphorescent powders containing zinc, beryllium, magnesium and tungstate. In November 1945, three years after his last significant exposure to beryllium, he suffered from cough and expectoration and lost weight rapidly. Radiography led to a tentative diagnosis of miliary tuberculosis. But sputum examination was negative for tubercle bacilli. Death was due to pulmonary granulomatous fibrosis.

Dr. John Agate, of the Department for Research in Industrial Medicine, who had examined the deceased, gave evidence that the pulmonary fibrosis was due to exposure to the dust of beryllium compounds. Asked by the coroner about prevention, he thought that the best course would be to abandon the use of beryllium wherever possible. It would be possible to extract the dust from processes, but he was not sure that safety would be thus secured. The deceased was exposed to risk by doing research on fluorescent lamps at a time when the delayed form of pneumonitis due to beryllium was not recognized. A representative of the employers stated that preventive measures had been adopted. New fluorescent powders which did not contain beryllium were being evolved. A verdict of death by misadventure was returned. Recent American reports show that the handling of beryllium compounds is attended by risk of dermatitis or pulmonary disease.

### International Congress of Ophthalmology

The Sixteenth International Congress of Ophthalmology will be held in London under the presidency of Sir Stewart Duke-Elder July 17 to 21, 1950. Any qualified medical practitioner may become a member. Relatives and friends of members will be welcomed as associate members and may attend the opening and closing ceremonies and all social functions. The official languages are English, French and Spanish, but any language may be used. The International Council of Ophthalmology has agreed on two main discussions on the following subjects: (1) "The Role of the Sympathetic System in the Genesis of Vascular Hypertension and Its Effect on the Eye," and (2) "The Clinical and Social Aspects of Heredity in Ophthalmology." Those desirous of participating in the main discussions or reading communications on other ophthalmologic subjects should communicate with Mr. Keith Lyle, International Congress of Ophthalmology, 45 Lincoln's Inn Fields, London, W. C. 2.

### Increase of Blood Transfusion

The Ministry of Health states that more donors gave blood to the National Blood Transfusion Service during the June quarter of this year than at any time since the war. In all, there were 98,055 donors, including 24,075 new ones. In the same period 30,497 persons joined the service—the highest number since March 1947. This brings the total number up to 377,304 for England and Wales. To provide for future needs of the service due to increasing demands, it is estimated that another 142,000 donors are required.

### Decline of Venereal Disease in British Army of the Rhine

The deep concern aroused in this country by the prevalence of venereal disease among the youthful soldiers of the British Army occupying Germany has been mentioned in a previous letter to THE JOURNAL. A deputation of Free Church leaders who recently visited the British Army of the Rhine now reports that young men have "not just been thrust willy-nilly into a kind of modern Babylon." A great improvement has taken place. Venereal disease has fallen to a remarkable degree, and every care is being taken of the soldiers by experienced men and women. Among the factors which have contributed to the improvement are the better conditions of the Germans, which has raised their morale. There is less inducement for a German woman to sell herself for food and cigarets, as she was eager to do when young soldiers first went to Germany. The black market then was rampant and the troops' rations of cigarets and chocolate gave them fantastic bargaining power. Fresh arrivals of the British Army for the first few weeks are now allowed to go to town only in the company of a non-commissioned officer. All sorts of facilities for social, cultural, moral and spiritual development have been liberally provided.

*(From Our Regular Correspondent)*

PARIS, Dec. 18, 1948.

### The Number of Doctors in France

At the request of the Council of the National Order of Doctors, the Ministry for Public Health has created a Commission of Medical Demography, in which the Ministry of National Education, the Home Office, the Ministers of Labor, of Public Health and Population, the National Order of Doctors, the Confederation of the Syndicate of Doctors and the Army Medical Corps will be represented. Mr. Magnin (Lyons) has been entrusted with inquiring from the district councils of the order; Mr. Levi (Ministry of Public Health) has the same mission of getting information from the services and the directors of the Ministry for Public Health. On October 14, Mr. Magnin reported the results of his study, limited to the metropolis. In 1900 there were 17,000 doctors; in 1939, 28,397 and in 1947 there were 30,754. Thus the ratio has passed from 1 doctor for 2,200 inhabitants to 1 for 1,300, which is equal to that of Belgium, but smaller than the ratio for Denmark, United States and Argentina and larger than the one for Mexico and Sweden. There is 1 general practitioner for 2,000 inhabitants and 1 specialist for 7,800. The number of physicians is higher in the districts with large cities, but for France as a whole there is an unsatisfactory distribution. An inquiry in twenty-two districts has revealed that 16 per cent of the practicing doctors are over 65 years of age (age at which they are eligible for pension), an important number still practice after 70, and the number of doctors under 40 years is equal to the number of those over 50. The number of medical students has increased from 7,336 in 1926 to 10,480 in 1938. There is a strong concentration in Paris, where half of the theses of France are submitted. Taking into account a diminution of about 38 per cent in the number of students (discontinuation of studies, girl students marrying) it is estimated that in 1953 13,500 students will have finished their studies. It is estimated that if in six years 6,200 doctors will have ceased practicing, there will be 40,000 doctors in 1955, 50,000 in 1960 and 60,000 in 1970. As from 1949-1950 measures are considered to restrict the admission of students for the study of medicine.

### Antibiotic Enzymes Rendered Specific Through Associated Cultures

J. Risler has studied the antibiotic potency of Aspergillus flavus with green sporulation (A. A. M. R. selected strain); cultivated in a Czapek-Dox medium to which peptone and glucose are added, it yields a metabolic fluid strongly antibiotic as regards numerous gram-positive and gram-negative microbes, but without any effect on the human or bovine bacillus of tuberculosis. By pursuing his research with German, Morel and others, he has obtained, through associated cultures of Koch's bacillus and of this mold, the elaboration of an enzyme strongly antibiotic for the tuberculosis bacillus. At the last meeting of the Academy of Sciences, the author presented his new method: on a twenty-one day culture of human virulent tubercle bacilli, developed on a Sauton or Massol-Breton medium, spores of A. flavus are inoculated; the tubercle bacillus culture medium is drawn off and replaced with the one of the mold. After five days in an incubator at 30 C., the A. flavus sporulation is very intense, and in the underlying medium an amber-colored pigmentation is seen, characteristic of the antibiotic enzyme. If some spores, taken from this associated culture, are inoculated again on a homogenous culture of the de Courmont's tubercle bacillus, after a fresh sporulation a clearing (under the mycelium area), sets in, which gains in depth little by little; this is the sign of the formation of the antibiotic enzyme, which may be activated by means of successive passages. The antibiotic potency of the enzyme from an associated culture is specific for Koch's bacillus, but it has no effect on Staphylococcus aureus. Guinea pigs inoculated with a human tubercle bacillus strain and treated either with the enzymic liquid originating from the pigmented area of the associated culture or with the enzyme filtrated, precipitated and purified, failed to present classical manifestation of evolutive tuberculosis on the ninetieth day. Out of 10 control guinea pigs, contaminated under the same conditions, 7 died between the thirty-fifth and the fifty-second day.

### *Fight Against Cholera*

The World Health Organization and the International Office for Public Hygiene have convened medical experts representing Egypt, India, Great Britain, Sweden and France, in Paris, to study the fight against cholera; among others present were Sir Aly Tewfik Shousha, Under-Secretary for Public Health (Egypt); Dr. C. J. Pandit, Secretary to the Indian Research Fund Association, and Dr. Bruce White, National Institute for Medical Research, London. The specialists recommend that studies on the endemicity be made on the spot and that teams of specialists, organized by the World Health Organization, be sent to make tests in those endemic regions. On the other hand, it has been recommended that experimental research be pursued actively in order to improve methods of prophylaxis. The experts recommend tests in endemic regions and threatened countries with the anticholeric vaccine, recently discovered by Major-General Sir Sahib Sokhey, which, in experimental research, appears to be ten times more effective than ordinary vaccines. The next discussion of the World Health Organization experts' committee regarding the revision of sanitary international conventions will be based on the recommendations of this group of specialists.

The next meeting of the experts for the fight against cholera will take place in a country where cholera is constantly present, in order to study territorial conditions and to profit by the experience of local experts.

### *Professor Roussy is Dead*

Gustave Roussy died on Sept. 30, 1948. He had been appointed professor of pathologic anatomy in 1925 and elected dean of the Paris Faculty in 1933. In 1937, he was appointed vice-chancellor of the Paris Academy, from which position he was relieved by the Vichy Government in 1940, as a consequence of the students' demonstration on November 11, but he resumed his appointment as from the liberation in August 1944. Since 1939 he had been a member of the Academy of Sciences. He was a Doctor Honoris Causa of several foreign universities. As a clinician, he was much interested in physiologic and anatomopathologic studies. Besides his many textbooks, his name is attached to numerous works on the pathologic physiology of the hypophysis and on the genesis of cancer; he has, in collaboration with J. Camus, described the part of the tuber cinereum and, with Dejerine, the thalamic syndrome. On his initiative was created the Cancer Institute, of which he was director, one of the most important research centers for this disease.

## TURKEY

*(From Our Regular Correspondent)*

Ankara, Dec. 7, 1948.

### Leprosy Control in Turkey

The early seventeenth century primitive leprosariums of Istanbul, Edirne, Konya and Zafranbolu have now fallen into ruin. Sultan Mahmud II (1765-1839) established the first large leprosarium in Istanbul-Scutari near the big Selimiye Barracks, where Florence Nightingale nursed the wounded during the Crimean War in 1856. In the nineteenth century Prof. Zambaco Pasha of the Istanbul Medical School was of the opinion that leprosy is not a contagious disease; in 1901 Prof. Suleyman Numan Pasha taught his students that it is an infectious disease and is not easily transmitted from man to man, contending that the Imam, who for many years lived among the unfortunates at the Scutari leprosarium, did not contract the disease.

Though the lepers come mostly from the eastern provinces of Kas, Erzurum, Agri and Van, which border on Russia and Iran, lepers have been found in the Sivas, Kayseri, Gaziantep, Marash, Hatay and Afyonkarahisar provinces. The two modern leprosariums have at present almost 400 inmates, all paupers from rural communities; no well to do leper has yet been found in an urban community.

Provincial health officers and city health officers are always vigilant against lepers, and besides the people themselves inform the health officer if they think that there is an afflicted person somewhere. The people so dread the disease that a woman just discharged from the leprosarium as cured, when on the way back to the village, was pushed by her husband over the brink of a precipice and fell to her death.

At the Istanbul and Elazig leprosariums chaulmoogra oil and methylene blue are used for treatment. Every second day the patients receive an injection of chaulmoogra oil and an intravenous injection of 1 per cent solution of methylene blue. For lepromas and ulcers a 20 to 30 per cent solution of trichloroacetic acid is used; also antiseptics like "rivanol" (2-ethoxy-6,9-diaminoacredine lactate), bismuth subgallate and a mixture of 40 per cent sulfamethylthiazole and 60 per cent urea, sometimes in the form of powder or ointment. Sulfonamide drugs have not been effective, and there have not been good results with penicillin or streptomycin. "Rubrophen" (trimethoxy-dioxy-oxotritan) has been tried, but better results have been obtained with a mild mercurous chloride lotion to which 1 per cent glycerin was added. One patient was given twelve vials of "promin" (sodium p,p'-diaminodiphenylsulfone-N,N'didextrose sulfonate), but because an import license had not been procured the treatment had to be discontinued; besides the price of this remedy makes its use prohibitive. The patients are given tonics and plenty of vitamins; their food rations are higher than those in other hospitals.

The samples of "diasone sodium" (disodium formaldehyde sulfoxylate derivative of 4,4'-diaminodiphenyl sulfone) which the Abbott laboratories forwarded to the Ministry of Health have been tried on different types of patients and have proved to be the best leprosy remedy available. A daily dose of two tablets of the drug for one hundred and twelve days was given to 3 patients suffering from lepra neurosa with severe necrosis, and for one hundred and seventy-six days to 3 patients suffering from the same manifestations. The absence of Hansen bacilli was always determined. During the treatment the patients complained of pain in the stomach and nausea but not sufficient to justify the discontinuance of the treatment. In 2 patients acute edema and erythematous pustules developed. It has been found that these untoward symptoms can be prevented if after a daily dose of two tablets of "diasone" for two months there is an interval of two weeks. The treatment with this drug did not in any way affect the urine or the hemoglobin count. In 3 patients the erythrocytes decreased 10 per cent. Some patients who in the beginning had been enthusiastic about the new remedy became despondent after two to three months and henceforth took it rather unwillingly. At the Elázig leprosarium 9 patients are at present undergoing the treatment with "diasone"; 3 patients have already improved, and it is believed that a complete cure will be effected with this drug, of which no bad effects have been observed.

If after being pronounced cured, a patient is found free of Hansen bacilli three times, with an interval of forty-five days each, he is discharged. Travel expenses are paid for by the hospital; the patient is given a certificate of health, is put on the train by a hospital attendant and returned to his family, which is informed of the arrival by telegram. The health officer of the respective district is also informed by telegram of the patient's arrival and his exact address. The discharged patients are followed up and at the slightest sign of a relapse are readmitted to the hospital. During the eight years a few readmissions have been recorded. The leprosariums are under the direction of and maintained by the Ministry of Health and Social Assistance. The specialist at the division of hygiene is in charge of all work connected with leprosy.

## BRAZIL

*(From Our Regular Correspondent)*

Rio de Janeiro, Dec. 6, 1948.

### Compulsory BCG Immunization

A federal law has been enacted about BCG immunization. This is the text of the law:

"Section I—The executive branch of the government is hereby authorized to take the necessary steps, through the National Service of Tuberculosis of the Ministry of Health, to promote in the entire national territory, whenever indicated, the BCG immunization of infants, children and adults against tuberculosis.

"Section II—The National Service of tuberculosis shall promote an intensive educational campaign on the safety and advantages of BCG immunization against tuberculosis, and for this aim shall seek the cooperation of the agencies of local government.

"Section III—Beginning two years after the enactment of this law, a certificate of BCG immunization shall be presented by all newborn infants about to be registered, children to be enrolled for school work, patients seeking hospital treatment, candidates for public services and men entering the armed forces. If this cannot be complied with, the person shall be urged to seek BCG immunization, which shall be facilitated whenever possible.

"Section IV—The executive branch of the government is also authorized to contract, through the National Service of Tuberculosis, with the Ataulpho de Paiva Foundation of Rio de Janeiro, and with other organizations with similar aims or similar technical equipment and personnel, for the preparation and furnishment of BCG immunization material, to be produced under the control of specialized technicians.

"Section V—A sum of 3 million cruzeiros [$150,000] is appropriated to cover the expenses of the services authorized by this law."

The Brazilian medical profession is strongly divided about the subject of this law, many doctors maintaining that it is not even clear whether this means compulsory immunization or not. It is also feared that the enforcement of such a law may be the cause of more difficulties for birth registration, school attendance and hospitalization, which are markedly insufficient in Brazil.

# Miscellany

## PITUITARY TUMORS

Four groups of tumors occur in the pituitary region. The one responsible for amenorrhea is a chromophil tumor; a predominance of eosinophils is found with that tumor. Amenorrhea does not develop until changes take place with a sort of dispituitarism.

Second and most common is the chromophobe adenoma, which develops much like an adenoma of the thyroid, since it develops in the anterior part of the gland which has to do with the endocrines. When the tumor becomes of sufficient size either to destroy or to invade part of the anterior lobe all the dispituitary symptoms occur. Also there is a peculiar change in the skin, which becomes thin. If the patient is a male the beard will become thin and sparse.

The third type is the basophilic adenoma (Cushing's syndrome). The odd changes which the patient goes through, include an increase in blood pressure and a striation of the abdominal skin. There is an excessive gain in weight. The patient may not have filling defects as a result of the growth because the tumors are not large. Then, too, the tumor may be associated with other endocrine gland disturbance, such as those of the adrenal. A headache can occur with all of them.

Probably most common is the glioma. As the tumor grows there is an erosion and flattening of the cella and as long as there is room for the tumor to settle into the sinus little pain is present. Once the tumor is enlarged pain situated back of the eye, between the eyes and sometimes in the transtemporal area, develops.

Fourth is the so-called craniopharyngeal pouch tumor, which originates from the stump of the pituitary gland. It may drop into the third ventricle just as well as grow downward into the sella. When it does papilledema and violent headache comparable to the ones produced by tumors of the brain occur.

QUESTION: Why do not histologically malignant brain tumors metastasize?

ANSWER: Most of these tumors of the gliomatous type are in the cortex and are at the end of the blood vessels. They represent lesions that do not come in direct contact with the large vessels except the meningiomas. The meningiomas are invariably incapsulated and they do not break off easily or throw off cells.

There are two tumors that do metastasize, the most common being the medulloblastoma, a cellular undifferentiated tumor that usually arises in the vicinity of the fourth ventricle, and these cells do break off and implant themselves on all of the surfaces of the arachnoid and down through the spinal canal. These tumors arise in the lobar area and out over the surface of the brain. These implants are carried with the cerebrospinal fluid as it is reabsorbed through the various villi. Their failure to metastasize like ordinary carcinomas I presume is due to the fact that they do not grow into blood vessels as these other tumors do.—Answers by Dr. Alfred W. Adson, Rochester, Minn., to questions at the Second Round Table Luncheon, Annual Cancer Conference, Denver, July 15, 1948, edited from material published in *Rocky Mountain Medical Journal,* November 1948, page 1015.

## VENOUS THROMBOSIS AND PULMONARY EMBOLISM

Modern prophylactic methods can materially reduce the incidence of postoperative thromboembolism. This decreased incidence is due primarily to the use of proximal vein ligation and/or anticoagulants, but recent improvements in pre- and postoperative care have also played a definite role. Allen and associates have been the foremost advocates of vein interruption. Heparin has been used most exensively in Sweden and "dicumarol" has been favored in this country by Barker and others. Each of these methods, or combination of methods, has its firm advocates, but experience has shown that any one of the three can be effective when properly used. . . .

These methods present serious problems. Routine prophylactic bilateral vein ligation entails an added operating room procedure. Many surgeons view with alarm large scale normal vein ligation, and there is reason to believe that edema of the legs and other complications occur in some individuals as a result. Routine prophylactic postoperative anticoagulants require very careful laboratory control if they are to be both safe and effective. This is especially true with "dicumarol," as the dosage must be individualized for each patient and plasma prothrombin activity must be determined daily during the treatment. This is a major technical and economic problem for the well equipped hospital and an insurmountable problem in the hospital with inadequate laboratory facilities. If the problem of thrombosis is approached statistically, only about 6 per cent of postoperative patients require prophylaxis, but there has been no proven method by which this relatively small group can be distinguished from those patients who will not have thrombosis. Our recent experience indicates that the prothrombin activity of the plasma in the postoperative period may serve as a helpful test in predicting those patients who are liable to thromboembolic complications.—Rachel S. Sandrock, M.C., and Earle B. Mahoney, M.D., Prothrombin Activity, *Annals of Surgery,* September 1948.

# Medical Motion Pictures

## FILM REVIEWS

**Cancer: The Problem of Early Diagnosis.** 16 mm., color, sound, 1,200 feet (1 reel), showing time thirty minutes. Sponsored by the American Cancer Society and the National Cancer Institute of the Public Health Service. Produced in 1949 and procurable on purchase ($150) from Audio Productions, Inc., 630 Ninth Avenue, New York 19, or on loan from State Cancer Societies, State Health Departments and regional depots of Association Films, New York, Dallas, Chicago and San Francisco.

This film was designed as the first of a series of motion pictures to emphasize for the general practitioner of medicine the importance of early suspicion, accurate diagnosis and effective treatment in the handling of cases of cancer. Opening with a short sequence showing Dr. Billroth performing the first gastric resection for cancer of the stomach (1881), the film moves rapidly to the modern attack on gastric carcinoma. In succession each of the most deadly forms of cancer—for example, that of the stomach, breast, large bowel, cervix and lung—is discussed. In each site the means of early suspicion, accurate diagnosis and effective treatment are shown and the mortality with late diagnosis graphically contrasted with the mortality with early diagnosis. The film should be of great interest and value not only as a means of reemphasizing important facts about cancer for hospital staffs and general practitioners but also for introducing the subject and giving an over-all view of the cancer problem to medical students. It is hoped that the succeeding films in the series will be as well planned, well organized and carefully produced and that there will not be a long delay in their release. The photography, animation and narration are excellent.

**Families First.** 16 mm., black and white, sound, 600 feet (1 reel), showing time seventeen minutes. Prepared by The New York State Youth Commission. Produced in 1948 by RKO Pathe, Inc. Procurable on loan within the State of New York from Supervisor, Film Library, New York State Department of Commerce, 40 Howard Street, Albany 7, and procurable on purchase from New York State Youth Commission, 30 Lodge Street, Albany, N. Y.

This motion picture is a dramatic portrayal of the relation of the home to the formation of character and behavior patterns in children, and the efforts of community organization to meet the needs of the family. A series of episodes in the everyday life of two contrasting families, one of the sharing and the other the nonsharing type, reveals ways in which the essential needs of children can be supplied. A child grows up only once and grows as the parents shape him. The film clearly depicts that children without a sense of security have no sense of responsibility. It illustrates that children seek to satisfy four fundamental needs, security, affection, recognition and new experiences, and that inadequate home training and friction between parents in front of their children may be underlying causes for juvenile delinquency. Throughout the film, emphasis is placed on environment alone rather than individual differences that contribute to the adjustment of the child.

The final purpose of the film is to be of assistance in developing children into healthy, happy and law-abiding citizens, and it can be effectively used with urban adult groups, such as parent-teachers' associations, civic and service clubs, high school and college students and juvenile delinquency officers. It lends itself well to a discussion of this most important subject. Technically, the film is well done.

# Medical Examinations and Licensure

## COMING EXAMINATIONS AND MEETINGS

### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* Various Centers, Feb., June and Sept. 1949. *Part II.* April 1949. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2, Pa.

### EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY, INC.: *Written.* July 15. Various locations. Final date for filing application is April 15. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Avenue, New York 27.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written.* Various Centers, Feb. 17. *Oral.* New York City, April 1-3. Sec., Dr. George M. Lewis, 66 East 60th Street, New York 21.

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral.* San Francisco, Feb. 8-10, 1949. New York City, March 23-25. Philadelphia, June 1-3. *Written.* Oct. 17, 1949. Final date for filing application is May 1. Asst. Sec.-Treas., Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: *Oral.* Chicago, June 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY, INC.: *Oral.* Chicago, May 8-14. Final date for filing application is April 1. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh 6.

AMERICAN BOARD OF OPHTHALMOLOGY: *Written.* Jan. 14. *Oral.* San Francisco, March 21-24; New York, June 11-15; St. Louis, Oct. 15-19; Boston, Dec. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

AMERICAN BOARD OF ORTHOPEDIC SURGERY. *Part I.* Various Centers, April and May. Sec., Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14.

AMERICAN BOARD OF OTOLARYNGOLOGY: New York, May 11-14; Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

AMERICAN BOARD OF PATHOLOGY: Boston, April. Final date for filing application is March 1. Sec., Dr. Robert A. Moore, 507 S. Euclid Ave., St. Louis 10, Mo.

AMERICAN BOARD OF PEDIATRICS: *Oral.* St. Louis, Feb. 18-20. Baltimore, May 7-9. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Rd., Rosemont, Pa.

AMERICAN BOARD OF PHYSICAL MEDICINE: Atlantic City, June 4-5. Final date for filing application is March 15. Sec., Dr. R. L. Bennett, 30 N. Michigan Blvd., Chicago.

AMERICAN BOARD OF PLASTIC SURGERY: Examinations are given in June and November of each year in the home town of applicants. Sec., Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: *Oral.* May. Final date for filing application is Feb. 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Written.* Various Centers, March 1949. Sec., Dr. J S. Rodman, 225 S. 15th St., Philadelphia.

AMERICAN BOARD OF UROLOGY: Feb. 1950. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18, Minn.

### BOARDS OF MEDICAL EXAMINERS

ALABAMA: *Examination.* Montgomery, June 28-30. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

ALASKA:* Juneau, March 1. Sec.-Treas., Dr. W. M. Whitehead, Box 140, Juneau.

ARKANSAS:* Little Rock, June 9-10. Sec., Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 9-10. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Examination,* Los Angeles, Feb. 28-March 3. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento.

CONNECTICUT:* Hartford, March 8-9. Secretary to the Board, Dr. Creighton Barker, 258 Church Street, New Haven.

DISTRICT OF COLUMBIA:* *Reciprocity,* Washington, March 14. Sec., Dr. George C. Ruhland, 4130 Municipal Building, Washington.

FLORIDA:* *Examination,* Jacksonville, June 26-28. Sec., Dr. Frank D. Gray, 12 N. Rosalind Ave., Orlando.

GEORGIA: *Examination.* June, Atlanta and Augusta. *Reciprocity.* Atlanta, June Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

GUAM: *Endorsement.* Agana, Last Friday of each month Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam, % F.P.O. San Francisco, Calif.

INDIANA: *Examination.* Indianapolis, June. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, 416 K. of P. Bldg., Indianapolis.

IOWA: *Examination.* Iowa City, June 13-15. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

KENTUCKY: *Examination.* Louisville, June 15-17. Sec., Dr. Bruce Underwood, 620 S. 3rd St., Louisville 2.

MAINE: Portland, March 8-9 Sec., Dr. Adam P. Leighton, 192 State Street, Portland.

MARYLAND: *Examination,* Baltimore, June 21-24. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore.

MASSACHUSETTS: *Examination.* Boston, March 8-11. Sec., Dr. George L. Schadt, 413 E. State House, Boston.

MISSISSIPPI: Jackson, June. Asst. Sec., Dr. R. N. Whitfield, State Board of Health, Jackson.

MONTANA: Helena, April 4-6. Sec., Dr. O. G. Klein, First National Bank Building, Helena.

NEBRASKA:* *Examination.* Omaha, June. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Building, Lincoln 9.

NEVADA: Carson City, May 2. Sec., Dr. G. H. Ross, 112 N. Curry Street, Carson City.

NEW HAMPSHIRE: Concord, March 10. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

NEW JERSEY: *Examination.* Trenton, June 21-24. Sec., Dr. E. H. Hallinger, 28 West State Street, Trenton 8.

NEW MEXICO: Santa Fe, April 11-12. Sec., Dr. V. E. Berchtold, 141 Palace Ave., Santa Fe.

NEW YORK: *Examination.* Various Centers, Feb. 1-4. Sec., Dr. J. L. Lochner, Jr., 23 S. Pearl St., Education Bldg., Albany.

OHIO: *Endorsement.* Columbus, April 5. *Written.* Columbus, June. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

PUERTO RICO: *Examination.* Santurce, March 1. Sec., Mr. Luis Cueto Coll, Box 3717, Santurce.

SOUTH CAROLINA: Columbia, June 27-29. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

TEXAS: *Examination.* Austin, June 16-18. Sec., Dr. M. H. Crabb, 209 Medical Arts Bldg., Fort Worth 2.

UTAH: *Examination.* Salt Lake City, July. Sec., Dept. of Registration, Miss Rena B Loomis, 324 State Capitol Bldg., Salt Lake City.

VERMONT: *Examination.* Burlington, Feb. 3-5. Sec., Dr. F. J. Lawliss, Richford

VIRGINIA: *Examination.* Richmond, June 17-18. *Reciprocity.* Richmond, June 16. Dr. K. D. Graves, 631 First St., S.W., Roanoke.

WYOMING: *Examination.* Cheyenne, Feb. 7. Sec., Dr. Franklin D. Yoder, Cheyenne.

---

* Basic Science Certificate required.

### BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ALASKA: Juneau, Feb. 21-26. Sec.-Treas., Dr. C. Earl Albrecht, Box 1931, Juneau.

ARIZONA: *Examination.* Tucson, March 15. Sec., Dr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

COLORADO: *Examination.* Denver, Mar. 2-3. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

CONNECTICUT: New Haven, Feb. 12. Exec. Asst., State Board of Healing Arts, Miss Mary G. Reynolds, 110 Whitney Ave., New Haven 10.

DISTRICT OF COLUMBIA: *Examination.* Washington, April 18-19. Sec., Dr. George C. Ruhland, 4130 Municipal Bldg., East, Washington.

FLORIDA: *Examination.* Gainesville, June 11. Sec., Mr. M. W. Emmel, University of Florida, Gainesville.

MINNESOTA: *Examination.* April, June and Oct. Sec.-Treas., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

OKLAHOMA: Spring of 1949. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: Portland, March 5 and June 18. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

RHODE ISLAND: *Examination.* Providence, Feb. 9. Chief, Mr. Thomas B Casey, 366 State Office Building, Providence.

SOUTH DAKOTA: Vermillion, June 3-4. Dr. G. M. Evans, 310 E. 15th St., Yankton.

TENNESSEE: Memphis, March 21-22. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

WISCONSIN: Madison, April 2.. Milwaukee, June 4. Sec., Prof. W. H. Barber, Ripon College, Ripon.

# Bureau of Legal Medicine and Legislation

## MEDICOLEGAL ABSTRACTS

**Charitable Hospitals: Liability for Negligence.**—This was an action for the benefit of Frank Erwin, deceased, for damages for malpractice and negligence of the defendant hospital. From an order dismissing the hospital, the plaintiff appealed to the Supreme Court of Michigan.

It is an admitted fact, said the Supreme Court, that the defendant hospital was organized for eleemosynary and charitable purposes and is being operated in accordance with those stated purposes. The doctrine of immunity of charitable hospitals from tort liability, held the Supreme Court, is firmly implanted in the law of Michigan, and we are not convinced that this doctrine should be changed by the court. Accordingly the judgment in favor of the defendant hospital was affirmed.—*In re Erwin's Estate, 34 N. W. (2d) 480 (Mich., 1948).*

**Drunkenness: Admissibility in Evidence of Chemical Tests for Intoxication.**—The defendant was found guilty of driving a motor vehicle while under the influence of intoxicating liquor. From an order denying his motion for a new trial, he appealed to the district court of appeal, fourth district, California.

One of the witnesses who testified during the trial was the physician who treated the defendant and the other injured persons the night of the accident. During the course of this treatment the physician, at the suggestion of the highway patrolman, took a blood sample from the defendant. The physician testified that he "did not believe" that he discussed the taking of the blood sample with the defendant and he was rather doubtful whether the defendant "knew anything much that went on . . . although he did answer questions" and responded "by doing as he was asked to do." The blood specimen taken was delivered to a Dr. Neal at 8:30 the next morning for analysis of the alcoholic content. After showing his qualifications in that field and explaining the tests actually employed in making the blood analysis, Dr. Neal, over objections, was permitted to state that he found the alcoholic content to be 3.5 mg. of alcohol per cubic centimeter; that that means "that the amount of alcohol in the blood has reached that measurement, and that is a measurement something like a weight or a volume like teaspoons or tablespoons of alcohol"; that "that much alcohol indicates a definite degree of intoxication. . . . Using a scale beginning with 0.5 mg., it is questionable whether there is any effect from the alcohol in the blood. At 1 mg. there is the least perceptible effect from the alcohol. At the level of 2 mg. the amount of alcohol is sufficient definitely to interfere with a person's ability to do skilled acts. At 3 mg. a state of distinct intoxication or distinct inability to perform ordinary acts is definite. At 4 mg. a person is dead drunk. He loses consciousness as a rule"; that "a person with a 3.5 mg. result would be definitely under the influence of intoxicating liquor . . ." and "his ability to drive an automobile safely on the highway" would be impaired; that "it would not be safe for him, a man with a 3.5 result, to be on the highway driving an automobile"; that he ran this test twice to "prevent experimental errors or to prevent an error in performance . . . and in both tests it came out 3.5."

It was the defendant's contention that this line of testimony should not have been admitted in evidence during the trial on the ground that the sample was taken without his consent or knowledge and while he was suffering from shock and cerebral concussion, and was therefore in violation of Article 1, section 13 of the state constitution and the fifth amendment to the federal constitution. In support of this contention, he cited a number of cases previously decided by the California courts.

Cases involving the admissibility of evidence as to scientific analytic tests for intoxication, said the court of appeal, based on alcoholic content of the specimen of some bodily fluid, such as blood or urine, or of the breath, are correlated in 127 A.L.R., p. 1513. It would appear that on the laying of a proper foundation such evidence is admissible where there is no other evidence of compulsion or entrapment; but where the accused is compelled to submit to such tests against his will, some states hold that it violates his constitutional right in that he may not "be compelled to give testimony against himself" and on proper objections the results of the test are inadmissible. Continuing, the court of appeal said that the privilege against self incrimination, however, does not preclude the introduction of physical disclosures a defendant is forced to make or the results of tests to which he has involuntarily submitted; that the privilege only protects the person from any forced disclosures made by him, whether oral or written; and that it is limited to the protection against testimonial compulsion. In *State v. Cram,* 176 Or. 577, 160 P. (2d) 283, where the facts were similar and the same question was presented, it was said that the admission of testimony concerning the alcoholic contents of a blood sample taken from an automobile driver following an accident and at a time when he was unconscious and under arrest and where there was a subsequent prosecution for manslaughter based on death as a result of such accident, was not a violation of defendant's constitutional privilege against self incrimination. In the circumstances here related, the court of appeal concluded, it cannot be said that the trial court erred in overruling the defendant's objection to the admissibility of such evidence. This and other contentions of the defendant being overruled, the conviction by the trial court was sustained.—*People v. Tucker, 198 P. (2d) 941 (Calif., 1948).*

**Malpractice: Liability of Physician for Morphine Addiction of Patient Following Administration by Physician.**—The plaintiff sued for damages alleged to have resulted from the malpractice of the defendant physician. The jury found in favor of the plaintiff, but the trial judge entered a verdict for the defendant. Accordingly the plaintiff appealed to the Supreme Judicial Court of Massachusetts.

On Dec. 25, 1939, the plaintiff was suffering from nausea, but the defendant, without any complaint of pain by the plaintiff and without any physical examination or questions as to a medical history, gave the plaintiff a hypodermic injection of morphine, which was repeated twice that day. Early in 1940 the defendant gave her another injection in similar circumstances, and in 1941 he gave her occasional injections, until by July she was receiving about two injections a week; by the end of August she was receiving an injection every day, by September twice a day and by October three times or more a day, until the plaintiff's husband ordered the defendant from the house and threatened to "clean him up." Thereafter the plaintiff became "jumpy and nervous," and two days later, "after telephoning about every doctor in Adams for morphine," she experienced a complete blackout and was taken to a hospital suffering from morphine addiction described as "one quarter the way along to confirmed addiction." The plaintiff testified that she had never stated that she had pain until after the defendant had ceased giving her the injections. In 1944 she had her gallbladder removed. She said that a stone was found and that after the operation the nausea she had had since 1939 ceased. There was medical evidence that the plaintiff's nausea was caused by her gallbladder trouble and that it was possible to have gallbladder trouble with nausea but without pain. Finally, there was expert evidence that it was not proper medical practice to administer morphine to a patient who complained of nausea but not of pain, or over a period of time when there was no pain involved or to continue giving morphine in the absence of a diagnosis of a condition that could not be cured.

On the basis of this evidence, said the Supreme Judicial Court, the jury could have found that the defendant, in administering morphine to the plaintiff over a long period of time with constantly increasing frequency until she became to a considerable extent addicted to the drug, failed to observe the standard of skill and care required of him as a physician. Continuing, the court said that it could not be ruled as a matter of law that the plaintiff was guilty of contributory negligence or that she assumed the risk of addiction. It is true, said the court, that the plaintiff knew she was getting the injections and that eventually she sought them, and she testified that by about the last of July she was "beginning to get a little sneaky—starting to lie" and did not always tell the defendant the truth about her condition. She also testified that she did not know what the defendant was giving her, although in July she had a "suspicion," and she knew it was something that was relieving her and making her feel "pretty high." The jury, said the court, could have found that she knew she was getting morphine, but they were not obliged so to find. Much less were they obliged to find that she knew at what point addiction would begin, or that at any time before addiction became a fact she had ceased to rely on the superior knowledge of the defendant as to the amount of the drug that could safely be taken over a period of time.

Furthermore, the court continued, the defendant was not aided by the provisions of the general law that "a physician may personally administer any narcotic drug at such time and under such circumstances as he, in good faith and in the legitimate practice of medicine, believes to be necessary for the alleviation of pain and suffering or for the treatment or alleviation of disease." This section, said the court, was intended merely to make it plain that physicians personally administering narcotics in good faith and in legitimate practice should be exempt from a series of penal provisions relative to the sale and distribution of narcotic drugs. It was not intended to relieve them from civil liability under principles of law applicable generally not only to physicians in all other matters relating to the practice of their profession but also to all those who hold themselves out as possessing peculiar skill and competence in other professions and trades. The Supreme Judicial Court therefore held that the judgment should be for the plaintiff but added that this decision rests on evidence of improper and unprofessional conduct on the part of the defendant leading to addiction in the plaintiff and that nothing contained herein need cause anxiety to an honest physician who administers narcotics to a patient in accordance with the prevailing standards of medical practice. Accordingly the verdict for the defendant was set aside and the verdict of the jury in favor of the plaintiff ordered to stand.—*King v. Solomon, 81 N. E. (2d) 838 (Mass., 1948).*

# Current Medical Literature

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

**Malformations of Heart Amenable to Blalock-Taussig Operation.**—Taussig reports on 600 patients of all ages with all types of malformations of the heart for whom the clinical diagnosis was lack of adequate pulmonary blood flow, and on whom the Blalock-Taussig operation was performed. The operation is of benefit to those patients in whom the structure of the heart is such that it is able to adjust to the altered circulation. This is the case in patients with the tetralogy of Fallot who have been greatly improved and who have an equally good chance of maintaining this improvement. The operation was also performed on 47 with atypical malformations of the heart with pulmonary stenosis and atresia. Improved by the operation were those with a cardiac contour similar to that of the tetralogy of Fallot with left axis deviation, those with partial rotation of the heart on its axis, possibly those with pulmonary stenosis and an auricular septal defect in the absence of a ventricular septal defect and a few with unusual arrhythmia. The cardiac reserve and the ability of the heart to adjust to the altered circulation was best demonstrated by the postoperative course of 220 patients who were discharged improved and followed for a period of more than two years. Less than 5 per cent of these patients have shown progressive cardiac enlargement or died of cardiac failure. Thirty per cent have shown no increase in heart size. Thirty per cent have shown increase in heart size during the first three weeks after operation and then have adjusted to the load, and 30 per cent have shown cardiac enlargement between the time of discharge and a six month check-up and thereafter have shown no further increase in heart size. The results from the use of the subclavian artery, as estimated by the oxygen saturation of the arterial blood, the red blood cell count and the hemoglobin level, have been as beneficial as when the innominate artery has been used for the anastomosis, and this former group of patients has shown less increase in the size of the heart.

**Stress and Electrocardiogram in Induced Hypoxemia Test.**—Burchell and his co-workers carried out seven hundred and thirty induced hypoxemia tests for the diagnosis of coronary sclerosis after the method of Levy, the patient breathing a mixture of 10 per cent oxygen in nitrogen. In selected cases the test has been of great assistance in the diagnosis of coronary insufficiency. When coronary sclerosis of clinical magnitude is present, one may expect a positive result in about 50 per cent of cases. Two cases are cited to indicate that a similarly severe degree of coronary sclerosis may be present in patients with a negative or positive reaction to the test. The conclusion is drawn that, in many cases, coronary vasoconstriction is an important factor in determining whether an area of injury develops within the myocardium. In practically all patients increased ventilation occurs, and apparently there is a rough correlation between the extent of increase in ventilation and the degree of arterial hemoglobin saturation. The degree of arterial hemoglobin saturation is not the main factor which determines whether a positive or negative reaction to the test occurs in persons with coronary sclerosis. A physiologically unsteady state is present throughout the whole period of the induced hypoxemia, and comparisons cannot be justly made to determinations wherein equilibrium has been established. The brief duration of the test is a safety factor. The period of exposure to low oxygen tension may be shortened from twenty minutes to fifteen without significantly reducing the percentage of positive results. Patients with moderate hypertension and cardiac enlargement apparently give a positive reaction to the test only if coronary insufficiency related to coronary sclerosis is also present. The electrocardiographic changes follow a pattern which is consistent with, and supportive of, the concepts of the dipole theory as they are related to a myocardial injury wherein the more seriously affected cells lie in the endocardial layer. The disturbed myocardial state giving rise to the electrocardiographic changes during the test may exist independently of the physiologic stimulus for pain.

**Aneurysm of the Coronary Arteries.**—Scott suggests that aneurysms of the coronary arteries be considered as localized or diffuse and that the localized be further classified into four main groups: congenital, mycotic-embolic, syphilitic and arteriosclerotic. All diffuse aneurysms of the coronary arteries appear to be on a congenital basis. A total of 47 localized aneurysms have been reported since the first report in 1812; they may be divided in 15 congenital, 12 mycotic-embolic, 6 syphilitic, 6 arteriosclerotic, 4 of other types and 4 unclassified. The common complications of the condition are rupture, thrombosis and associated myocardial disease: When a localized aneurysm occurs, the left coronary artery is the more frequently involved and the condition is usually single. In a diffuse aneurysm, the right coronary artery is more commonly affected. There are no pathognomonic clinical findings. Men are much more frequently affected than women. One case of coronary aneurysm in a man aged 84 is reported; there were no cardiac complaints during life, and at autopsy there was observed an anomalous coronary circulation with multiple aneurysms, the largest of which measured 10 by 8.0 by 8.0 cm. The case is of particular interest as an illustration of the extent to which an abnormality can be present in the heart without causing symptoms.

Duo Liquid Adhesive: Its Uses in Neurosurgery. R. B. Cloward.—p. 313.

**Operation for Herniations of Nucleus Pulposus.**—Gurdjian and Webster review observations on 196 patients who had pain low in the back with sciatic radiation and who were operated on during a six year period. In 28 patients no disk protrusion was found. Among these 28 there were 12 with varicosities of the outgoing root. In 7 patients it was thought that there was root compression by contiguous tissue and in 8 others the relationships appeared normal. "Pantopaque" (ethyl iodophenylundecylate) or iodized oil U.S.P. myelography was carried out in 31 patients, but only in 21 did the myelographic and operative findings correspond. Every patient had roentgen studies of the spine, and in 27 significant coexisting spinal abnormalities were noted. In 121 patients operation consisted of hemilaminectomy and exposure of the fourth and fifth interspaces on the affected side. Bilateral laminectomy was done in 23 cases, and combined hemilaminectomy at the fourth and fifth interspaces on the affected side with fusion of the lumbosacral spine was carried out in 52 patients. The fusion usually consisted of a tibial graft, cancellous bone and osteoperiosteal graft. The nonlaminectomized side was mainly used for the graft. Most of the patients with fusion were ambulatory in two weeks. Results obtained by operation in 80 patients were excellent or good in more than two thirds of the patients, fair in another 20 per cent and poor in 12 per cent. The authors conclude that in most cases operation may be deferred in the first attack of pain low in the back with sciatica, but that massive ruptured disk with severe neurologic defect deserves immediate operative treatment.

**New Pregnancy Test.**—The new pregnancy test which Garrett has devised was suggested by results he obtained in the treatment of amenorrhea with estrone. The test has been used with slightly varying technic on some 250 patients without a single incorrect result. It consists of an intramuscular injection of three doses of estrone in oil, 1 mg. each, over a period of five days in certain selected patients. Failure to menstruate within twenty-four hours after the last injection is interpreted as a positive test for pregnancy. The test is inexpensive and simple to perform in the office without the use of animals or the aid of an outside laboratory. The greatest shortcoming of this test is that it is not applicable to a patient who is bleeding. As the test has been used on only 4 women approaching the menopause caution should be used in the interpretation of results in such patients until more data are available.

### American Review of Tuberculosis, New York

**58:**139-254 (Aug.) 1948

Effect of Phenylhydrazine in Experimental Tuberculosis. H. J. Corper and M. L. Cohn.—p. 230.
Tuberculosis in the Feebleminded. P. A. Theodos.—p. 237.

**Streptomycin in Chronic Tuberculosis.**—The two types which furnish the principal material for this report are: (1) chronically unstable tuberculosis of limited extent, which has continued to be active and to produce positive sputum in spite of prolonged treatment by conventional methods; the chronically unstable course of disease in these patients cannot be adequately explained on the basis of persistent visible cavity or bronchoscopically visible endobronchial tuberculosis alone; this group of patients has been designated as "grumblers"; (2) subacute and chronic disseminated nodular pulmonary tuberculosis, which has failed to respond to treatment by bed rest. Streptomycin has produced temporary improvement in most patients in the group of "grumblers." The principal evidence of this was the reduction or elimination of tubercle bacilli in sputum and gastric contents. Response has not been uniform, and relapses have already been observed in a small group of patients. Response of subacute and chronic disseminated nodular tuberculosis to streptomycin appears to be unequivocal.

**Cavernostomy.**—Cavernostomy according to Rockey and his associates is open drainage of a tuberculous cavity, which attacks the focus of the infection itself and leaves this part of the lung exposed to direct handling. In this method the tuberculous cavity heals by sloughing its caseous wall, which is removed with the dressing. The procedure is not new, but it has been modified by many surgeons. The authors perform this operation in one or two stages. If the overlying lung tissue is atelectatic and the pleural layers are fused, the operation can be performed in one stage, as was done in 10 of the 22 cases in which the authors performed cavernostomy. If the pleural layers are not adherent, the wound is packed with washed iodoform gauze for one week, after which time the cavity is opened at a second stage operation, as was done in 12 of the series. The cavity should be localized with the help of posteroanterior and lateral roentgenograms, as well as fluoroscopic examination in the same position in which the patient is to be placed on the operating table. Tomograms are also helpful in the localization of the lesion. The overlying skin area can be marked with intradermal injection of methylene blue or by other means. The overlying ribs are removed and the cavity is unroofed as widely as possible. The approach may be anterior, posterior or lateral, but should be wherever the cavity is nearest to the chest wall. There is a striking difference in the result of the cases with bilateral active disease as compared to the ones with active disease limited to the operated side. Ten of the patients had active disease in both lungs; 6 are dead. Of the 4 living patients, only one is well in the sense that the pulmonary disease is controlled. In the 12 cases with unilateral active disease, only 4 are dead. Of the 8 living patients, 4 are well with the disease controlled, wounds clean or healed, and no tubercle bacilli demonstrable in the sputum. Four are clinically improved with the pulmonary disease probably controlled, and tubercle bacilli are discharged in the sputum only occasionally. Thus 12 of 22 tuberculous patients in whom the prognosis seemed hopeless are alive and 5 are well. Another 5 patients are clinically improved, but 2 of these probably will not get well. However, even in these 2, life has been extended and symptoms have cleared to a great extent. The indications for cavernostomy in these 22 patients were: (1) bilateral, far advanced disease with controlled contralateral side and one or more large cavities present on the active side; (2) unilateral disease presenting the same type of disease on the active side as noted, for which more extensive surgical treatment was contraindicated because of a low respiratory capacity; (3) existence of a residual cavity under a thoracoplasty where revision of the thoracoplasty or excisional surgery was contraindicated; (4) bilateral, far advanced disease with the disease active on both sides and one or more cavities present on the operative side.

## Bulletin of the Los Angeles Neurological Society

**13**:129-180 (Sept.) 1948

Treatment of Tuberculous Meningitis with Streptomycin: Report of Case. H. M. Cuneo.—p. 171.
*Birth Primacy and Idiopathic Epilepsy. J. M. Nielsen and F. O. Butler.—p. 176.

**Neurologic Manifestations of Lupus Erythematosus and Periarteritis Nodosa.**—According to Sedgwick and Von Hagen lupus erythematosus and periarteritis nodosa are members of a poorly understood group known as the "collagen diseases." These diseases involve essentially the dispersed connective tissues (hence they are "system diseases"), and for this reason any organ in the body can be affected. Since the nervous system is not exempt, the presenting symptoms may be of a neurologic nature. The case records of all Los Angeles County Hospital patients in the past ten years who were suspected of having had either disease were examined by the authors to determine whether any consistent neurologic pattern could be established as an aid to diagnosis. They say that all of the nervous system lesions of each disease can be explained (*a*) directly by focal vascular disease resulting in occlusion of hemorrhage and (*b*) indirectly by reason of renal involvement resulting in hypertension and/or azotemia, or by hemorrhage from thrombopenia. Five cases of lupus erythematosus with involvement of the nervous system are presented: The first showed toxic psychosis and meningeal reaction; the second neuronitis including albuminocytologic dissociation in the spinal fluid; the third focal vascular central nervous system lesions; the fourth cerebral hemorrhage due to thrombopenia, and the fifth Sydenham's chorea followed shortly by lupus erythematosus and a toxic psychosis. Five cases of periarteritis nodosa with involvement of the nervous system are presented: One of these presented a picture of a true polyneuritis presumably due to generalized mononeuritis; 2 others mononeuritis multiplex; a fourth focal cerebral vascular lesions followed by mononeuritis multiplex, and the last occlusion of retinal artery, retinal hemorrhage and probable multiple cerebral thrombosis. Because of their disseminated pathologic changes no consistent neurologic syndrome can yet be defined for either disease. Lupus erythematosus manifests itself neurologically chiefly by central nervous system syndromes, while periarteritis nodosa chiefly affects various peripheral nerves.

**Birth Primacy and Idiopathic Epilepsy.**—Nielsen and Butler say that in a previous study of birth sequence as related to etiology of "idiopathic" epilepsy slightly over 100 cases were reported from private practice in which it was shown that about 60 per cent of the patients were firstborn. When a group of 992 epilepsy records became available in a home for feebleminded, a further investigation of this problem was undertaken in order to determine whether birth and birth trauma played a role in the causation of epilepsy. After exclusion of all cases of postnatal causation and those with deficient data there remained 780 for analysis. There were 279 firstborn and 501 of subsequent births. The incidence of known birth trauma was essentially the same in firstborn and others. On the other hand, of all epilepsy in the group 35.8 per cent occurred in firstborn children. As there was an average of 4.2 children per family and as the remaining 64.2 per cent of cases of epilepsy must be distributed among the remaining 3.2 siblings, the average per sibling of those subsequently born is 20 per cent. The ratio of 35.8 to 20 gives 1.79 to 1. The chances of a firstborn child's having epilepsy is therefore 1.79 or little short of twice that for a sibling (of subsequent birth) in this group.

**Effect of Fever on Hepatic Function.**—Observing the behavior of several hepatic function tests in various disorders during the war in Italy, Hicks and his associates gained the impression that abnormal results occurred frequently in conditions other than infectious hepatitis and led them to suspect that fever exerted an important influence on the rate of sulfobromophthalein sodium clearance. This suggested the importance of studying the effect of artificially induced fever on hepatic function. Such a study has been completed on patients on the wards of the University of Virginia Hospital. The patients studied fell into four groups: (1) those with acute infectious hepatitis, (2) those with tertian malaria, (3) those with primary atypical pneumonia and (4) those with miscellaneous conditions. The choice of tests was limited by the circumstances under which the studies were performed. The sulfobromophthalein hepatic function test was performed as modified by Mateer and others, and the cephalin-cholesterol flocculation test was done according to the method of Hanger. The authors found that abnormal sulfobromophthalein retention and abnormal results of cephalin-cholesterol flocculation tests occur frequently in disorders other than infectious hepatitis. The highest incidence of abnormal cephalin-cholesterol flocculation reactions occurred during convalescence in a group of patients with atypical pneumonia. In all groups the incidence of abnormal sulfobromophthalein retention was much higher on days when fever was present. Fever induced by artificial means was associated with diminished sulfobromophthalein clearance, and it appears probable that diminished sulfobromophthalein clearance is due to impaired function of the cells in the liver. The temperature of the patient at the time the test is performed must be considered in the interpretation of the bromsulfalein test.

**Sodium Bicarbonate and Excretion of Salicylate.**—Williams and Leonards say that since Smull and others in 1944 demonstrated that bicarbonate decreases the serum level of salicylate there has been renewed interest in the advisability of administering sodium bicarbonate during salicylate therapy. On the basis of studies the authors made on this problem they conclude that the administration of alkali to rats receiving sodium salicylate has no influence on the gastrointestinal absorption of this drug. The oral administration of bicarbonate to dogs receiving sodium salicylate causes a decrease in the serum salicylate level. This decline can be accounted for by the large increase in the excretion of salicylate in the urine. Sodium bicarbonate increases the clearance of salicylate four to nine times in a dog to values approaching the glomerular filtration rate. In human beings the action of bicarbonate on the salicylate clearance is not nearly so great. The salicylate clearance in human subjects is approximately equal to the urea clearance, but in the presence of administered bicarbonate the salicylate clearance rises above the urea clearance figure and also approaches the glomerular filtration rate. Sodium bicarbonate has no significant effect on the binding of salicylate by the plasma proteins of dogs or human beings. Salicylates are excreted in the urine in the unchanged form and also as conjugates with glycine and glycuronic acid. In dogs given intravenous injections of sodium salicylate, 75 per cent to 90 per cent of the total salicylate is excreted in the free form. In human subjects given salicylate orally, only 30 to 50 per cent of the total salicylate is excreted in the free form. The administration of sodium bicarbonate mainly increases the output of the unconjugated salicylate.

**Onycholysis Due to Nail Lacquer.**—Winston and Sutton encountered within a short period of time several women with onycholysis of all or most of the fingernails. After a brief study it became apparent that this type of onycholysis was caused by the newly introduced cosmetic preparations of plastic adhesive intended to keep colorful nail lacquer in place. Within a few months of their commencing the use of such substances, patients, who applied, respectively, "perma-nail," "nail-on" and "ever-on" noted thickening of the distal nail bed under the free margins of the nails and progressive, proximal separation of the nail accompanied by longitudinally streaked, brownish discoloration. The ingredients usually present in these special base coats are solutions of synthetic rubber of the Buna N type such as "perbunan" 35N560 modified by a phenol-formaldehyde type of resin such as "durez" 11078 or "bakelite" BR 17620, and dissolved in methyl ethyl ketone. Since the onychial damage done by various brands was clinically identical, it is assumed the chemical is similar in each. When the adhesive was left off, regrowth of the nails did take place. The collection of 4 examples of a "new disease" in a few weeks of a dermatologic practice suggests that many cases are occurring.

**Typhoid in Inoculated Soldiers.**—Tribby and his associates present observations on this problem in Italy and French Morocco. Eberthella typhosa was cultured from 45 and Salmonella paratyphi B from 10 inoculated soldiers in French Morocco and Italy. A small outbreak of typhoid in an infantry company was studied intensively. Two possible sources for the outbreak were found: (1) polluted water and (2) spreading by food handlers. Some soldiers drank unchlorinated water, believing that they were completely protected by antityphoid vaccination. This false sense of security appeared to be shared not only by enlisted men and line officers but by some medical officers as well. The dangerous belief of complete protection may lead to unnecessary risk. The authors recommend early seizure and chlorination of captured foreign water supplies, especially in view of the possibilities in modern warfare that bomb hits might mix sewage and drinking water. The continued need for the consumption of waters which are potable bacteriologically should be better emphasized.

Metastatic Malignant Melanoma of Lung.—p. 408.

**Coexisting Tuberculous and Meningococcic Meningitis.**—Riley presents a history of a man aged 26. What at the onset appeared to be an uncomplicated case of meningococcic meningitis terminated fatally with a tuberculous infection of the meninges, and was further complicated by the recrudescence of a malarial infection that the patient had contracted during his service in Sicily and Italy. The author reviews the literature, collecting cases that have been reported since 1911. Most of these case reports are from the foreign literature. The case reported here is the first to be reported from American sources, and is approximately the thirty-fourth case of its type in the literature. The source of the tuberculous meningitis in the author's patient remains a mystery. No visceral focus of tuberculosis was found in any of the organs examined. The clinical and pathologic evidence in the reported case suggests that the meningococcic infection may have activated a latent tuberculous focus.

Mesenteric Venous Thrombosis.—p. 444.

**Radioactivity and Urinary Tract Calculi.**—Cristol and his co-workers report a patient with a vesical calculus, multiple prostatic calculi and polycythemia vera. In an effort to bring the blood hematocrit level within normal limits prior to surgical treatment, it was decided to subject the patient to radioactive phosphorus therapy and thereafter to observe any changes in the size and configuration of the calculi. The first dose contained 6 millicuries, and the second, administered five months later, 10 millicuries. Periodically during the seven month period before operation, the calculus was observed radiographically and cystoscopically and appeared to grow larger. The bacterial and chemical constituents of the urine were also repeatedly examined. When the hematocrit reading appeared optimal, suprapubic removal of the vesical calculus, together with a revision of the vesical neck, was undertaken. The patient made an uneventful recovery and left the hospital free from urinary symptoms three weeks after operation. The authors suggest that in addition to the dramatic and graphic representation of stone formation, the employment of the radioactive element may prove to have many worth while uses in the study of formation of calculi in the urinary tract. This method might serve as a check on various proposed methods of preventing formation of additional stones. It gives an opportunity to observe, for example, the effect of an acid ash diet on the formation of alkaline stone. It also suggests the study of the effect of radioactive materials on associated infections of the urinary tract. The possible effects of residual radioactivity in calculi on the containing tissues are also under investigation. This is apparently the first recorded case of removal of a radioactive calculus.

Nutritional Factors Affecting the Toxicity of Halogenated Hydrocarbons: Review. L. L. Miller.—p. 194.

**Clinical Aspects of Occupational Cancer.**—Hueper points out that about one hundred and fifty years have passed since the demonstration of soot as a carcinogenic agent and that about seventy-five years have gone by since it was shown that arsenic, tar and crude paraffin oil have such properties. In recent decades many other physical and chemical agents, which are part of the industrial environment, have been recognized as carcinogenic agents. There are indications that the entire width and variety of the exogenous carcinogenic spectrum is not known and that during the coming years new agents related to occupational activity and industrial production may be discovered to be carcinogenic. Physicians engaged in industrial practice could be of great help in discovering carcinogenic agents if they would scrutinize all cancers occurring in workers for potential occupational causation. The author discusses the incidence of occupational cancer, known data on carcinogens and the treatment of occupational cancer. He also emphasizes the need of periodic examinations of workers in certain occupations.

**Neurosis in Various Occupations.**—Smith and Hightower attempted to determine whether there exist differences in the incidence of functional disease among patients of various occupations. A control study was made of 300 patients consecutively admitted to the Mayo Clinic. The following occupation groups were studied: clergymen, dentists, farmers, housewives, lawyers, nuns, physicians, railroad engineers and school teachers. An additional study was made of a group each of Jews and unmarried women. Jews were studied because among them the incidence of neuroses is declared to be high, and the unmarried women were studied mainly as a control for the occupational group of nuns. The authors gained the impression that about a fourth of all adult patients examined at the clinic receive a diagnosis solely of neurosis and that the incidence of neuroses is somewhat higher among female than among male patients. The incidence of neuroses among patients of the Mayo Clinic may be slightly less than that among patients as they are examined by their home physicians, because probably more of those whose conditions are severe or complicated are referred to the clinic. The authors feel that the low incidence of neurosis in railroad engineers (9 per cent) may be partly explained by the fact that these men are older than were the members of most of the other groups. As persons become older, they tend to become less emotional. Most of the neurotic patients were somewhat younger than were members of the groups as a whole. Railroad engineers usually work as firemen for a long period and the chances are that if they are emotionally unstable or neurotic they will not be offered promotion to the status of engineer. Farmers gave the next lowest incidence of diagnoses of purely functional disease. Persons who do manual work seem to be less inclined to be neurotic than those who do other types of work. In public school teachers purely functional disease was found in 33 per cent. Functional plus organic disease was found in 21 per cent of the total. Thus 54 per cent of the teachers had some type of functional disease. This is the highest percentage of diagnoses of neurosis of all occupational groups. Percentages for other groups were 39 for clergymen, 36 for housewives and 42 for nuns. The incidence of neurosis in Jews was no higher than in the controls. The study confirms that the incidence of neuroses among persons of various occupations differs greatly.

**Roentgen Treatment of Anthrax Infections.**—Riebeling treated 36 Mexicans, 22 males and 14 females, with infections produced by Bacillus anthracis, by roentgen irradiation. In 16 cases the disease appeared to be local or regional; systemic manifestations were present in 16, and 4 patients were in a state of coma when first seen. Twenty-seven patients presented a single lesion, 8 presented two lesions and 1 presented four lesions. Seven patients had been treated previously by cauterization, by intravenous injection of bovine serum and by penicillin, respectively, without improvement. Patients with mild disease were treated by irradiation every twenty-four to forty-eight hours, the dose per field varying from 18 to 85 roentgens. In very ill patients treatment was instituted with a small dose to each field, usually 18 roentgens every twelve hours. The interval between treatments was increased after one or two days to twenty-four hours and later to seventy-two hours. Because of surface irregularities and the extent of involvement, some patients were treated through multiple fields. Treatment was given with radiation of 140 kilovolts, with filtration of 2.0 mm. of aluminum to 0.25 mm. of copper and aluminum. The usual skin distance was 30 cm. All patients showed a prompt response to irradiation. Bacillus anthracis disappeared from the exudate from the primary lesion and general and local manifestations subsided. All patients were known to be free of symptoms within fifteen days to two months. No complications incident to treatment were observed.

**Roentgen Rays in Treatment of Infections.**—According to Kelly and his co-workers, adequate dosage of roentgen ray, living tissues and a suitable time factor are essential to obtain beneficial effects in treating infections by irradiation. A girl aged 7 with tetanus was treated with large doses of antitetanus serum, phenobarbital, penicillin, streptomycin, tribromoethanol, orange juice and glucose. Roentgen treatment was started on the third day, as there was apparently no response to the previous measures. The patient was free of evidences of toxemia at the end of the first week, four days after irradiation was initiated, and fully recovered at the end of the second week. Because of the many methods of treatment employed it is impossible to attribute the result to any one of these. Roentgen therapy can be recommended for tetanus in conjunction with other measures. Roentgen treatment was practiced in a girl aged 15 who had her right humerus shattered; a severe gas infection developed despite the administration of penicillin and anti-gas gangrene serum and the use of surgical cleansing. Suspicious tissues were removed from the anterior part of the arm, the axillary area and the anterior chest wall. Little tissue was removed from the posterior chest wall, as the patient was too seriously sick to permit the manipulation required for this procedure. The tissues posteriorly were as badly infected as were the tissues anteriorly, but much of them recovered fully. There was good union of the main upper and lower fragments of the humerus. Amputation of an extremity is not necessary for the successful treatment of gas gangrene if roentgen treatment is promptly instituted. Removal of tissues during the acute toxic phase of the disease is unnecessary. Due to the latent period of the effect of roentgen rays from eighteen to twenty-four hours, treatment must be started early. The authors are not convinced that the antibiotic will take the place of roentgen rays in the prevention or treatment of acute infection, but these drugs may be used simultaneously without ill effects. Sulfonamide drugs should not be given in conjunction with irradiation. No patient should be allowed to die of bacterial toxemia without benefit of roentgen treatment.

**Endometriosis.**—Burnside operated in his private practice during the years 1938 to 1947 on 101 patients with endometriosis. There were 18 who had all of their ovarian tissue removed. Of the remaining 83 patients 12 had a subtotal and 43 a complete hysterectomy. Of the total number, 44 were left with the possibility of becoming pregnant and 7 actually became pregnant. Of the 65 women who could be followed up to the time of this study, 2 required a second operation, 2 had pain that was severe enough to warrant roentgen ray castration and 3 are taking testosterone intermittently to control pain. Measures that help prevent endometriosis include correction of retrodisplacements, stenosis and fibroids; the use of an impervious material over the abdominal incision while doing cesarean operations, and also the practice of discarding the instruments that were used before closing the abdomen. It may be advisable to use testosterone in small doses in the treatment of young women with endometriosis, in order to keep the disease in abeyance. The patient should be advised of her condition and of the problems with which she is faced. This is especially true in the case of young, single women who wish to be married and have children. There are times after palliative surgical treatment when it is preferable to give a castrating dose of roentgen rays rather than subject the patient to another operation.

**Post-Thrombotic Syndrome of Lower Extremity.**—Linton and Hardy report 49 patients, 31 women and 18 men, between the ages of 24 and 69 years with thrombotic sequelae in one or both lower extremities. A definite history of a preexisting deep venous thrombosis of the lower extremities was given by 46. The post-thrombotic syndrome is characterized by pain, edema, varicose veins, stasis cellulitis, stasis dermatitis, pigmentation and chronic ulceration. It is believed that this syndrome develops as a result of the sustained increased pressure in the veins of the lower extremity due to incompetent valves of the deep, communicating and superficial systems of veins following canalization of the deep veins. Interruption of the femoral vein distal to the profunda femoris branch, ligation and stripping of the long saphenous vein, and, in addition, the short saphenous vein if it is varicosed, have been performed in 84 extremities presenting the post-thrombotic syndrome in various stages. The common femoral vein should not be interrupted. The importance of removing the entire main saphenous trunks is emphasized. None of the extremities was injured by the procedure, indicating that the superficial femoral and the saphenous veins are not necessary collateral venous channels in the post-thrombotic extremity. The postoperative complications were few and not serious, and the mortality rate was zero. The results of follow-up varying from one to sixteen months in the 84 extremities subjected to this form of treatment were encouraging, but further years of observation are necessary to determine the definite value of this method.

**Gastric Carcinoma and Anacidity.**—Hebbel and Gaviser determined the presence or absence of achlorhydria in 284 patients, 205 men and 79 women, with carcinoma of the stomach. Gastric resection was performed in all cases, and the resected specimen was available for reexamination. Two hundred and forty-three patients (86 per cent) had achlorhydria or maximum acid values below 30 degrees; 220 patients (77 per cent) had achlorhydria or maximum acid values below 20 degrees, and 185 patients (65 per cent) had achlorhydria. Achlorhydria was uniformly present only in association with tumors of Borrmann type I (9 cases) and these totaled but 3.2 per cent of the series. For tumors of Borrmann types II, III and IV, there was no constant association of either achlorhydria or hypochlorhydria. Twenty-two (28 per cent) of the type II tumors, 16 (34 per cent) of the type III tumors and 61 (41 per cent) of the type IV tumors were associated with free acid on gastric analysis. In each of these groups the maximum acid values were below 20 degrees in about one third of the cases and exceeded 20 degrees in about two thirds of the cases. While these data follow others in showing the predominance of reduced secretory capacity, as of the time the diagnosis is made, in a group of cases of gastric carcinoma, they also emphasize the fact that no range of acidity precludes the disease. Emphasis on the examination of persons with achlorhydria or hypochlorhydria in order to detect most early gastric cancer is valid only to the extent that achlorhydria with cancer also means achlorhydria before the cancer appears.

**Craniosynostosis.**—Ingraham and his co-workers report 50 children with all varieties of premature closure of the cranial sutures for which the term "craniosynostosis" has been used. Twenty-nine children, 24 boys and 5 girls, presented premature closure of the sagittal suture. There were 8 patients, 5 girls and 3 boys, with premature closure of the coronal suture, 4 patients with premature closure of the sagittal and coronal sutures, 3 with premature closure of sagittal and lambdoid sutures and 6 with that of all cranial sutures. Twenty patients (40 per cent), 7 of the sagittal group, 3 of the coronal group and 10 with two or more sutures fused, were retarded to some extent before surgical treatment was practiced. Of the 44 patients treated surgically, 20 patients received treatment before the age of one year. Because of the rapid growth of the brain during the first year of life, it is to be expected that the best results from surgical treatment will be obtained during this period. This has been confirmed in the author's cases. Many patients came to the hospital at ages varying from 3 to 7 years and in these little was to be expected from any surgical procedure. In spite of this there was definite improvement in the patient's behavior at home. Eleven patients (25 per cent) showed retardation after operation. In general, the prognosis for mental development of a patient with premature closure of the cranial sutures treated under the age of 1 year is excellent, but if synostosis is evident at birth, surgical therapy should not be delayed more than a few weeks. Linear craniectomy with polyethylene film inserted over the bone edges to retard regeneration of bone has been adopted as the operation of choice. There have not been operative deaths, wound infections or serious complications.

**Glyceryl Trinitrate in Raynaud's Disease.**—Fox and Leslie present the histories of 2 patients in both of whom several clinicians had confirmed the diagnosis of Raynaud's disease and previous treatments had been unsuccessful. The first patient was a woman, aged 40. Since the onset of her illness in the winter of 1943-1944 her condition had been diagnosed on three occasions as Raynaud's disease. Many therapeutic approaches have been attempted, including vitamins, the parenteral use of papaverine and the parenteral use of alcohol. With the exception of the last, all were not beneficial. The alcohol injections gave fleeting relief. In October 1947, the patient came under the medical care of the authors. A right unilateral stellate ganglion block had been done previously. This caused Horner's syndrome, and the right hand became pink and warm. The patient was referred to the Mayo Clinic for a possible sympathectomy. Dr. A. W. Adson suggested that surgical treatment be delayed and that the topical use of 2 per cent glyceryl trinitrate in wool fat three times daily be tried. Since using the glyceryl trinitrate preparation, the patient has noted that her hands are now persistently pink in color rather than white. The amount of swelling of the fingers has decreased. The ulcer on the tip of the right index finger has healed, and the gangrenous area on the same finger has decreased. The authors later resorted to the topical application of 2 per cent glyceryl trinitrate in wool fat in a woman, aged 30, in whom Raynaud's disease had proved refractory to various treatments. Here again the glyceryl trinitrate in wool fat effected great improvement.

**Presumptive Malarial Pneumonia.**—Heilig observed 64 cases of pneumonia that were complicated by malaria. He reports cases in which treatment was carried out in such a way that the effects of sulfonamide drugs and penicillin on the pneumonic process could be clearly distinguished from those of antimalarial therapy. Five cases of presumptive malarial pneumonia involving one half to three lobes are reported. While physical and roentgenologic findings were those of a pneumococcus pneumonia, in 4 of these cases the fever was remittent. The leukocyte counts on admission varied between 5,500 and 20,000. The differential picture showed moderate monocytosis. The sedimentation rate of erythrocytes was considerably increased. Malarial ring forms were found in 2 cases; the reaction to the malaria flocculation test was or soon became positive in all of them. Slight or moderate enlargement of the spleen was present without exception. As a contrast, a case of penumonia merely associated with malaria is described. The most important feature, common to all of the cases of presumptive malarial pneumonia, was that neither sulfonamide drugs nor, in 2 of them, penicillin had any effect on either the general condition, the pneumonic consolidation or the temperature, whereas antimalarial therapy promptly brought about defervescence, resolution and surprisingly quick general improvement. These cases represent a little known syndrome of combined pneumococcus and malarial infection, in which the elimination of the pneumococci does not lead to clinical improvement because the presence of plasmodia maintains fever and prevents resolution. The importance of recognizing the malarial factor is emphasized, as timely institution of antimalarial therapy proves life saving. The fact that malarial parasites were found in only 2 of the 5 patients may be due to previous treatment with antimalarial drugs. The seasonal incidence of presumptive malarial pneumonia is determined by the pneumonia season, not by the maximum incidence of malaria.

Placenta Praevia Accreta. W. N. Chisholm.—p. 470.

**Thoracoplasty and Pregnancy.**—McIntyre studied the influence of thoracoplasty on pregnancy, particularly delivery, in 12 women. There were 7 multiparous and 5 primiparous patients. A two stage, seven rib thoracoplasty was performed on each patient included in this study. With one exception, this operation was done on the left side of the chest. Except for 1 patient who received this operation when she was three and one-half months' pregnant, the interval between thoracoplasty and pregnancy varied from one to ten years. The average duration of labor was fifteen hours and fifteen minutes. Instrumental delivery was performed in 6 patients. Slight dyspnea was observed in 2 patients toward the end of the second stage of labor. The placenta in each instance was expelled complete and no excessive bleeding or puerperal sepsis occurred. Observations on these patients indicate that the occurrence of distressing dyspnea during labor after thoracoplasty is largely hypothetic and that interruption of pregnancy is not indicated in these women. Advice regarding pregnancy in patients with thoracoplasty cannot be given without reservation. Sufficient time should elapse to insure healing of the lesion before permitting pregnancy. Given a patient, however, with tuberculous lung lesions adequately and anatomically collapsed by thoracoplasty, coexisting pregnancy need not necessarily be regarded as a severe imposition on the maternal organism.

**Erythrocyte Sedimentation Rate in Pregnancy.**—Obermer describes the procedure which he used for the determination of the sedimentation rate of erythrocytes and gives figures obtained in 283 determinations on 88 healthy pregnant women and in 1 in whom the fetus had died in utero about the thirty-fourth week. In the majority of normal pregnant women sedimentation velocity increases slightly as early as the fifth or sixth week; from the eighth week onward there is a regular increase in the velocity, up to a maximum at the fortieth week; after labor the velocity falls steeply. In four weeks the sedimentation declines to almost normal values and at the end of eight weeks the normal values of the nonpregnant state are reached. Curves plotted from the values obtained in the woman whose fetus died in utero at about the thirty-fourth week show a steep fall in the velocity at the thirty-seventh week (practically to the normal level for the nonpregnant state). There were no clinical grounds for suspecting any abnormality in the pregnancy.

**Transorbital Leukotomy.**—Freeman points out that less than a year after the introduction of leukotomy by Moniz in 1936, Fiamberti proposed a simplified operation on the frontal lobes by way of the orbital plates. Freeman's studies on cadaver in 1945 confirmed the fact that the orbital plate could be easily perforated without danger to structures within the orbit and without encountering large intracranial vessels and that the thalamofrontal radiation could be severed fairly far anteriorly without disturbance of the cortex except to a minimal degree. Early in 1946, 10 patients were subjected to transorbital leukotomy with encouraging results. Two years later 6 of them were fully restored and only 1 was in hospital. The series has been extended since then to more than 100 cases in various mental hospitals. It has been demonstrated that frontal leukotomy can be performed safely and effectively by the transorbital route of Fiamberti during the phase of coma following electroshock. Recovery may be rapid and undesirable changes in personality are minimal. The operation is a minor one and may be performed by the psychiatrist provided he has thoroughly familiarized himself with the technic and landmarks through previous practice on the cadaver. The operation has been most effective in certain patients in whom tension was a prominent feature of the illness and whose illness was becoming chronic in spite of more conservative therapies.

Rh Blood Types in Australian Aborigines. R. T. Simmons and J. J. Graydon.—p. 113.

*Aneurysms of Splenic Artery, with Report of 2 Cases and Review of Literature. J. I. Tonge.—p. 119.

Urinary Excretion of 17-Ketosteroids and of Corticosteroid-Like Hormones by Newborn Infant. E. M. A. Day.—p. 122.

*Thiamine in Pink Disease. E. H. M. Stephen.—p. 124.

**Aneurysms in Splenic Artery.**—Tonge presents 2 cases of aneurysms of the splenic artery. The literature contains reports of 145 cases. Arterial degeneration, congenital defects of the vessel wall and endocarditis seem to be the most likely etiologic factors. Syphilis, trauma, splenomegaly, increased portal pressure and periarteritis nodosa are comparatively rare causes. The association of pregnancy with the formation of these aneurysms is more apparent than real. The clinical features vary according to whether rupture has occurred or not. Even in the former case, the clinical picture is not clearcut, as the aneurysm may rupture by a single or "two stage" process. The outlook is usually rather poor. Before rupture of the aneurysm, the treatment of choice is splenectomy with removal of the segment of the splenic artery from which the aneurysm has arisen. After rupture, heroic surgery and blood transfusion are needed. A case of twin aneurysms occurring in the splenic artery of a single woman is reported. Fatal hemorrhage from rupture of one of these aneurysms occurred during exploratory laparotomy. The second case report is of the rupture of an aneurysm of the splenic artery in an elderly man, which occurred while he was undergoing treatment for congestive cardiac failure. This rupture was of the "two stage" variety.

**Thiamine in Pink Disease.**—Stephen says that in the past he had treated pink disease (erythredema polyneuropathy) with oral administration of adequate doses of vitamin B preparations. He observed the prompt response resulting from intramuscular injection of thiamine in a patient treated by Dr. Dalton. He employed a preparation that contains 50 mg. of thiamine per cubic centimeter and injected intramuscularly every fourth day 3 minims (0.18 cc.) of this solution. The 8 patients in whom this treatment was employed made a satisfactory progress.

Revision of Freud's Theory and Method? D. Dreyfuss.—p. 49.

**The Psychosomatic Concept.**—Deutsch surveys opinions on the psychosomatic concept. Psychosomatic medicine is the systematized knowledge of how to study bodily processes which are fused and amalgamated with emotional processes of the past and the present. Certain personalities can be related to certain psychosomatic disorders. The author discusses the psychosomatic aspects of asthma, rheumatoid arthritis, atopic dermatitis, peptic ulcers and colitis. He stresses that understanding the personalities involved in psychosomatic disorders can prevent a wrong approach to the patient. The anticipation of the kind of behavior which the patient will show toward the persons who treat and handle him can be of great value. It can protect the physician against showing an inadequate response to the behavior of the patient, because in understanding the personality pattern he will not take this behavior pattern at face value, since it has unconscious motivation and is a symptom of the disease.

## Archives Françaises de Pédiatrie, Paris

5:225-336 (No. 3) 1948

*Congenital Transplacental Tuberculosis of Icteric Form. R. Debré, Mrs. Furiet-Laforet and P. Royer.—p. 225.
Research on Dehydration and on Ratio of Some Electrolytes in Blood and Urine of Dyspeptic Infants. P. Rohmer, R. Sacrez, Miss Leroux and M. Lagoutière.—p. 332.
Duodenal Ulcers and Pseudo-Ulcerous Duodenal Bulbitis in Children of School Age. J. J. Dubarry.—p. 240.

**Congenital, Transplacental, Icteric Tuberculosis.**—Debré and his co-workers report a case of congenital, transplacental, icteric tuberculosis in an infant aged 6 weeks who was hospitalized because of icterus and hepatosplenomegaly. There was choluria, fever and poor general condition. The feces were not discolored. Examination of the blood showed lowering of the cholesterol esters, reduced proteinemia and prothrombinemia. The father of the infant was in good health but the mother had severe bilateral pulmonary tuberculosis of eight years' duration. Koch's bacillus was observed in her sputum in the fourth month of pregnancy. Delivery was uneventful and the infant was separated immediately from the mother, who never saw or embraced him. Jaundice was observed in the infant during the first days of life. At the age of 1 month the infant vomited and lost weight. He died six days after admission to the hospital. Necropsy revealed a large number of tubercles in the lung with many acid-fast bacilli. The pedicle of the liver was thickened and consisted of a conglomeration of enlarged lymph nodes. Whitish-yellowish granulations were disseminated in the parenchyma of the lungs, in the liver and in the spleen. The conclusion seems to be warranted that death of the infant resulted from hepatosplenic icterogenic tuberculosis of congenital origin. The disease of the mother, the nature of the anatomic lesions and the abundance of acid-fast bacilli on the sections left no doubt concerning the tuberculous nature of the disease. The removal of the infant from the mother immediately after the delivery, the early manifestations of the disease during the first days of the life of the infant, the essentially splenohepatic and pulmonary distribution of the lesions and the characteristic caseation of the lymph nodes at the liver hilus confirm the congenital nature and the transplacental origin of this tuberculosis, although the placenta was not examined microscopically.

*Convulsive Eclampsia in Its Relationship to Diencephalon: Therapeutic Trial with Intravenous Procaine Hydrochloride. H. Ezes.—p. 1987.
Receptiveness of Nervous System to Infection. Le Fèvre de Arric. —p. 1998.

**Procaine Hydrochloride in Eclampsia.** — According to Ezes, in pregnant women endocrine disorders may affect the vegetative centers of the diencephalon. In cases of mild disease this involvement may be manifested by functional disturbances of a peripheral organ such as the kidney, and, in grave, by convulsive attacks. The sympatheticotonic hormones are predominant in the eclamptic patient. The concept of eclampsia as a labile, temporary, functional disturbance of the neurovegetative system, probably of the diencephalon, caused by substances which exert a sympatheticotonic effect, suggested the use of a sympathicolytic treatment. Accordingly, 6 women with eclampsia were treated by intravenous administration of procaine hydrochloride. In 1 of these patients a convulsion took place eleven hours after the birth of her fourth child; it was followed by coma. There was a rise in the arterial pressure and papilledema. Both arterial and retinal pressures were reduced by the intravenous administration of 10 cc. of a 1 per cent solution of procaine hydrochloride without epinephrine. Convulsive attacks did not recur, and vision improved after a second injection of this solution. The number and the intensity of the convulsions were influenced favorably by procaine hydrochloride in the 5 other patients, 4 of whom had convulsions during pregnancy and 1 had convulsions during labor. In 3 of the 5 the eclampsia was primary and was controlled more rapidly than in the 2 others, in whom the convulsive attacks were preceded by a preeclamptic state. This treatment is indicated particularly for primary eclampsia during labor and post partum. In other instances it should be combined with other measures directed at the control of exogenous factors.

*Study on Presence of Poliomyelitic Virus in Muscles of Mice Inoculated with SK Virus in Preparalytic Period of Poliomyelitis. J. Sanz Ibáñez. —p. 319.

**Poliomyelitic Virus in Inoculated Mice.**—Sanz Ibáñez produced paralysis in two groups of mice given intraperitoneal inoculation of a suspension of either brain or of leg muscles of mice from an original group in which mice were killed at different hours after inoculation with poliomyelitis virus. Mice in the original group did not show any symptom of the disease at the time they were killed. In mice in the two groups poliomyelitic paralysis developed either on the sixth day after inoculation when the material used was that of animals which had been killed four hours after inoculation, or on the third day when the material was that of animals which had been killed sixty-three or sixty-seven hours after inoculation. The results of the experiments show: (1) the presence of the virus in the brain and in the leg muscles of inoculated mice in the original group as early as four hours after inoculation, and (2) that the period of incubation and of appearance of paralysis in animals of the second and third groups shortens in relation to greater number of hours of life of the original group after inoculation.

Problems of Pathology of Liver. W. Eger.—p. 317.
*Essential Hypertension of Pulmonary Circulation and Its Familial Incidence. F. Lange.—p. 322.

**Hormones for Carcinoma of Prostate.**—Wildbolz treated 61 patients with carcinoma of the prostate by daily oral administration of 5 mg. of diethylstilbestrol in tablets. The drug was tolerated well by nearly all patients. A few had vertigo and rash and were given intramuscular injections of alpha-estradiol dipropionate. Results were satisfactory in 30, who showed considerable clinical improvement, having no difficulty or pain. There was moderate improvement in 8; 7 were failures, and in 16 the follow-up was too short for any conclusions. In patients with satisfactory results treatment must be continued for the rest of their lives in order to prevent recurrences. These may occur in spite of continued treatment, and in these cases administration of estrogenic substances may be combined with castration. In patients in whom castration has been performed prior to treatment with estrogenic substances, this latter treatment may be practiced in case of recurrence, and again clinical improvement may result. While administration of estrogenic substances neutralizes the male sex hormones, castration prevents their formation. It has been established by five years' experience with estrogenic substances that a cure cannot be obtained with estrogenic substances alone and that satisfactory results are temporary only. Hormone therapy, therefore, should not be instituted at once after diagnosis of carcinoma of the prostate has been made. Radical perineal prostatectomy is suggested, for carcinoma in the early stage and repeated transurethral resection without administration of estrogenic substances may be sufficient in patients whose only symptom consists of retention of urine. Administration of estrogenic substances may be instituted in patients with rapidly progressing carcinoma, with pain due to metastasis and rapid deterioration of the general condition. Experience suggests that administration of estrogenic substances may increase the duration of survival.

**Hypertension of Pulmonary Circulation.**—Lange reports 1 case of essential hypertension of the pulmonary circulation in a woman aged 54 with edema of the lower extremities and cyanosis of the face, hands and feet. Dyspnea was almost absent. The blood pressure was low. The number of red blood corpuscles was increased to 5,200,000. There was a loud systolic murmur over the aorta and the secondary pulmonary sound was accentuated. Auricular flutter and retardation on the right side with corresponding disturbance of potential were revealed by the electrocardiogram. Death occurred from heart failure in a few seconds. Excessive hypertrophy and dilatation of the entire right side of the heart were revealed on necropsy. There were few vascular changes in the lungs, with hyperplasia of connective tissue of the intimal layer of the median and small arteries. The carotid gland was increased considerably on both sides. The systolic murmur over the apex of the heart and over the pulmonary artery was not caused by organic changes of the cardiac valves, but by dilatation of the rings of the valve resulting from the dilatation of the decompensated heart. The clinical aspect and the anatomic observations were similar to those described by Romberg for which the term primary pulmonary sclerosis was coined. The morphologic changes in the walls of the pulmonary vessels, however, did not correspond with the excessive hypertrophy of the right heart. It is possible that a functional rise of blood pressure in the pulmonary circulation is responsible for the changes in the pulmonary vessels and for the hypertrophy of the heart. For this condition the term essential hypertension of the lesser circulation is suggested in analogy to that of the greater circulation. This partial essential hypertension may be familial. The author examined 42 members of a family of 186 whose genealogic tree could be followed back to 1729. Eighty-two of the 186 relatives presented a reddish blue discoloration of the skin. Thirty of the 42 examined persons had this discoloration of the skin, and 10 of them presented a loud second pulmonary sound. Thirteen of 18 adults presented considerable enlargement of the conus arteriosus. As a result of this enlargement the left auricle was displaced upward so that it formed an upward edge. This anomaly, and the cyanosis, became manifest only after puberty. In the majority of the members of the family the electrocardiogram did not show any definite changes. The blood pressure was normal in all, except for 3 who presented a hypertrophy of the left in addition to that of the right side of the heart, suggesting essential hypertension of the systemic circulation in addition to that of the pulmonary circulation. Although these two conditions do not depend on one another, they may occur simultaneously.

### 78:845-868 (Sept. 4) 1948. Partial Index

*Significance of Electromyography and Electroencephalography in Diseases of Extrapyramidal-Motor System. K. Hartmann and M. Monnier. —p. 845.
Supporting Pad Treatment for Static Disorders of Foot. H. Feriz. —p. 850.
Lyspamin and Some Additional New Derivatives of Nicotinic Acid. H. Suter.—p. 853.

**Electromyography and Electroencephalography in Motor Disturbances.** — Hartmann and Monnier report 4 patients, 1 woman aged 40 with postencephalitic parkinsonism and 3 men aged between 44 and 71 years with postencephalitic parkinsonism associated with rigor and tremor, with degenerative disease of basal ganglions associated with tremor in the absence of rigor, and with choreiform twitching of the fingers and the shoulder associated with postapoplectic right hemiplegia respectively. Electromyographic and electroencephalographic recordings were made in these 4 cases before the administration of the new spasmolytic "parpanit" (diethylaminoethyl-1-phenylcyclopentane-1-carboxylate hydrochloride) and twenty-five to fifty minutes after the subcutaneous administration of 0.05 Gm. of this drug. The study of the bioelectric phenomena in the muscles and in the brain revealed that in case of rigor asynchronous electric activity occurs only after a certain lapse of time during voluntary movements and continues after muscular relaxation. "Parpanit" causes a more rapid occurrence of asynchronous activity during voluntary movements, and it disappears more rapidly at the end of the muscular action. Clinical improvement of the motility corresponds with this "normalization" of the electromyogram. In cases of tremor with rigor the electromyogram is characterized by groups of synchronous discharges whose frequency may be six to eight seconds and whose amplitude increases during voluntary movements. These discharges may be overbridged by the gradually occurring asynchronous activity; that corresponds with the clinical observation that the tremor decreases during voluntary movements. Under the influence of "parpanit" the amplitude and the duration of the rhythmic discharges decrease; after muscular relaxation they even may disappear completely for some time. The tremor without rigidity in degenerative diseases of the basal ganglions does not differ electromyographically from that of patients with Parkinson's disease. The electromyogram of choreiform unrest after postapoplectic hemiplegia is characterized by rhythmic discharges of low frequency (2.5 seconds). They may become manifest only with voluntary muscle contraction. Their amplitude increases considerably under the influence of "parpanit." These differences indicate that the genesis of postapoplectic choreiform motor unrest and of Parkinson's tremor is not identical. The electroencephalogram of patients with postencephalitic parkinsonism reveals a deficient blockage of the alpha rhythm by light acting as stimulus, and deficient coordination of the electric activity of both hemispheres of the brain. Abnormally slow rhythm may occur occasionally. The improvement of these phenomena resulting from the administration of "parpanit" may correspond clinically with an attenuated bradyphrenia. There is no relationship between the rhythm of the electroencephalogram and that of the electromyogram. The apparent coordination of the two rhythms is merely an artefact which is caused by the tremor of the frontal and temporal muscles.

---

**Anatomy of the Human Body.** By Henry Gray, F.R.S. Twenty-fifth edition, edited by Charles Mayo Goss, M.D., Professor of Anatomy, Louisiana State University School of Medicine, New Orleans, La. Fabrikoid. Price, $14. Pp. 1478, with 1263 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1948.

This book has been known to generations of medical students and practicing physicians, and this new edition retains the familiar aspect; even the cover has been changed from maroon in the previous edition to the dark green cover of former years. The present editor is Dr. Charles M. Goss, professor of anatomy at Louisiana State University School of Medicine, New Orleans; however, the six associate editors of the previous edition again contribute chapters, and their work has been left almost intact. This statement applies also to the former editor-in-chief, Dr. Warren H. Lewis, and refers particularly to his work on embryology.

The text has been revised and illustrations replaced or added where research has offered new material. The illustrations, which have always been excellent, are even more outstanding in this edition, as is the text, apparently because a better grade of paper was used. The list of references at the end of the chapters is more extensive and, while designed to stimulate the interest of the student in further reading, many of the references may be used to authenticate statements in the text.

When Henry Gray, a lecturer on anatomy at St. George's Hospital Medical School in London, published the first edition of this book in 1858, it covered 750 pages and contained 363 figures. The present edition, published ninety years later, covers 1,478 pages and contains 1,263 illustrations. Gray was 31 years of age when this book first appeared. His career of great promise was rapidly cut short when he contracted smallpox while he was caring for a nephew who had that disease.

***The Psychology of Abnormal Behavior: A Dynamic Approach.*** By Louis P. Thorpe, Ph.D., Professor of Education and Psychology, the University of Southern California, Los Angeles, and Barney Katz, Ph.D. Cloth. Price, $6. Pp. 877, with illustrations. The Ronald Press Co., 15 E. 26th St., New York 10, 1948.

This book addressed to undergraduate students is a comprehensive, although simplified, presentation of the subject. It succeeds in its attempt to be both dynamic and eclectic, and its format, typography and figures are such that even beginning students will find it easy reading. The authors go beyond the descriptive level and give an excellent formulation of the background dynamics currently held for each of the subjects which are discussed. There are well chosen and typically representative cases which illustrate the various syndromes. The necessarily simplified and condensed discussion of the wide scope of material surveyed is expanded by an up-to-date bibliography as well as separate case, author and subject indexes. The authors have expanded the text's usefulness further by the inclusion of 44 tables of relevant statistics and lists of other pertinent data. There is a most helpful 19 page glossary of technical terms. The contents are presented in eight parts, and, despite an 877 page bulk, it is a book which can be recommended to students of the psychology of abnormal behavior.

**Methods of Vitamin Determination.** By B. Connor Johnson, Associate Professor of Animal Nutrition, Division of Animal Nutrition, University of Illinois, Urbana, Illinois. Paper. Price, $3. Pp. 109, with 19 illustrations. Burgess Publishing Co., 426 S. 6th St., Minneapolis, 1948.

This book presents a detailed outline of the assay methods used in the determination of vitamins in food and biologic substances. The principles of the microbiologic, colorimetric and fluorometric methods of analyses are explained in two chapters. There is no complete description of the vitamin or a detailed list of its chemical and physical properties. Nevertheless, this handy laboratory manual lists in detail satisfactory assay procedures for sixteen vitamin and vitamin-like substances, with a short chapter on the amino acids. Wherever applicable, the biologic, chemical, microbiologic and physical methods are described in detail for the vitamin. The specific limitations of the procedure and the influence of interfering substances on the assay methods of vitamins are not fully described. Emphasis has been placed on microbiologic and chemical methods.

**Vaccination par le B.C.G. par scarifications cutanées.** Par L. Nègre et J. Bretey, chefs de service à l'Institut Pasteur de Paris. Préface du Professeur A. B. Marfan. Second edition. Paper. Price, 180 francs. Pp. 115, with 10 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris $6^e$, 1947.

The book deals with the transcutaneous method of BCG vaccination introduced by S. R. Rosenthal. From an experimental study in animals and human beings, the authors verify the efficacy of this method as far as the rapidity of developing a positive tuberculin reaction is concerned and in its protection against a virulent reinfection. But, as Professor Marfan stated in the preface, to judge the value for the human species of a method of premunition against tuberculosis a very long period is required; however, the results already obtained justify every hope. Reviewing the various other methods used for BCG vaccination, the authors point out that after oral administration the percentage who reacted to tuberculin after vaccination to 30 mg. of the organism is low, around 30 per cent, whereas by the subcutaneous and intradermal methods the conversion is high, up to 100 per cent. The complications of ulcers and abscesses are so frequent that the popularity of BCG vaccination may be undermined.

In France, where BCG vaccination first began, the procedure was losing its popularity since the oral method had been used for the main part and the conversions were so low.

Experimentally in guinea pigs the intradermal, subcutaneous and transcutaneous methods were compared, and it was found that after the transcutaneous method antituberculosis resistance is established by the ninth day, progresses to the twentieth day and remains at that level for thirty to forty-five days. Three years after vaccination, the guinea pigs still have a manifest resistance against tuberculosis but not as pronounced as after one to two years. As compared with the other two methods, immunity appeared sooner and lasted longer.

In infants, the reaction to tuberculin after vaccination disappears after two and one-half to three and one-half years when 20 mg. per cubic centimeter suspension is used. When a 50 mg. per cubic centimeter suspension is used, the reactions to tuberculin persist for three to three and one-half years. To augment further the duration of the reaction to tuberculin, 75 mg. per cubic centimeter is now used.

The authors recommend scarifying with the usual type of scarifier used in France for vaccinia. This looks like a pen point with one sharp edge. Varying with the age of the child, crosslike scarifications 0.5 cm. long are made through a drop of vaccine; two such crosses are made in newborn infants to ten in adults. After a few seconds, slight bleeding will occur. A small piece of gauze saturated in the vaccine is then placed over the scarified areas and left there for twenty-four hours. At present double hatches are made 1 cm. apart and 1 cm. long. In some children, as many as 4 such double hatches are made. This method is preferred in France to the multiple puncture method as recommended by Rosenthal, since the average practitioner has been using the scarifier for vaccinia for a long time. Rosenthal says that when the multiple puncture method was used with thirty punctures made over an area of 3½ by 1 cm. and with a vaccine 15 mg. per cubic centimeter, 99.7 per cent positive reactors were obtained in newborn infants, who continued to react to tuberculin to the extent of 90 per cent after four to four and one-half years. No dressings whatsoever were used.

Some 70,000 vaccinations by the transcutaneous method (scarifying) have now been performed in France. There have been practically no complications following the method except for occasional lymph node enlargements and a rare local accumulation of pus.

With the mounting interest in BCG vaccination in this country, the method of applying the vaccine should become the interest of those who are to use it. This book presents both experimental and clinical evidence that the transcutaneous method of vaccination is one of choice since it is easy to apply, is practically devoid of complications and produces an earlier and more lasting resistance against virulent reinfection.

**The Nursing of Tuberculosis.** By O. V. Buxton, S.R.N., and P. M. Macculloch Mackay, S.R.M.N. With a foreword by Richard R. Trail, M.C., M.D., F.R.C.P. Cloth. Price, $2. Pp. 124, with 23 illustrations by Nora Lewis, S.R.N. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2; John Wright & Sons, Ltd., 42-44 Triangle West, Bristol 8, England, 1947.

This book was prepared for graduate and student nurses engaged in the care of tuberculous patients. Its main object is "to enable nurses to give the person suffering from tuberculosis all the care that is necessary to promote recovery wherever possible and to maintain the 'chronic' case in as comfortable a state as circumstances allow." The first four chapters are devoted to etiology, variations of the disease, pathology and anatomy of the chest. These are discussed briefly so as to give the nurse a general understanding of them. In chapter 5 the symptoms of pulmonary tuberculosis are related, and their treatment is presented in chapter 6. In the two succeeding chapters the sanatorium regimen is presented and special methods and remedies are discussed. A short chapter is devoted to the psychologic aspects of tuberculosis. Various forms of collapse therapy are presented, with special emphasis on the role of the nurse in each of them. Complications of pulmonary tuberculosis and associated diseases are discussed adequately. A chapter on special tests includes the technic of examining sputum, urine, pleural fluid, cerebral spinal fluid and feces. The tuberculin skin test, blood sedimentation rate and vital capacity determination are also presented in this chapter.

Extrathoracic tuberculosis, particularly that involving bones and joints, lymph nodes and the genitourinary system, is included. Under prevention it is pointed out that tuberculosis is spread in two ways: one, by dissemination of bacilli from persons with contagious disease to those in contact with them, and, two, by contaminated milk. Methods of preventing such dissemination are outlined. The authors state that "until some vaccine is discovered which will protect the body against the infection, the most we can do is to increase the resistance of the individual so that his body is able to withstand the invasion of the bacillus when it attacks him." Rehabilitation of the tuberculous is well presented in the last chapter.

The authors assume that in England nearly everyone becomes infected with tubercle bacilli. This is in sharp contrast to the present situation in the United States, and therefore the method of approach in tuberculosis control differs somewhat in the two countries. Aside from such differences, the fundamental knowledge contained in this book is useful to nurses everywhere.

**Give Them a Chance to Talk: Handbook on Speech Correction for Cerebral Palsy.** By Berneice R. Rutherford. Paper. Price, $2.75. Pp. 116, with illustrations. Burgess Publishing Co., 426 S. Sixth St., Minneapolis 15, 1948.

This book is eminently practical. Chapters on "Description of Cerebral Palsy," "Description of Speech Differences," "Background of Speech Therapy," and "Problems of Personal Adjustment" are included. It is written in nontechnical language. A certain paucity of detail in one or two chapters presupposes some previous knowledge of the subject on the part of the reader. Chapters on "Therapy for the Development of Speech" and "Special Problems in Speech Therapy" are excellent. Many suggested procedures and exercises will be helpful in working with children having cerebral palsy and with other speech sufferers. Visual and kinesthetic as well as auditory cues are stressed. Interesting diagrams illustrate points discussed in the text.

Since the material is so practical and well presented another edition, expanded somewhat and in better dress, would be desirable.

**Medical Advisors Manual, The American Legion.** Paper. Pp. 96. National Public Relations Commission, The American Legion, 1608 K St., N.W., Washington, D. C., 1948.

As its title indicates, this booklet is a manual for medical advisers published by the American Legion. It is a guide to the Veterans Administration and to other factors which influence the treatment of the sick or disabled veteran. The Ten-Point Program of the American Medical Association is reprinted in full. The medical advisers to the Legion are given many responsibilities. There are ten points under the aims and purposes of the National Advisory Board, eleven points under a similar tabulation of suggested responsibilities and duties of the department (state) medical adviser and thirteen more for the post medical adviser. An interesting statement occurs in the introductory paragraph of the section on the department medical adviser: "Matters of health and education fall into the category of state's rights. Hence, even in a national campaign for health, the key to success must be found in each state. The golden key for your department is in your hands" (page 16, paragraph 1). The pamphlet contains much varied information on rehabilitation, medical education, psychiatry, medical rehabilitation, postwar surgery, conditions which may need care (a list two pages long of conditions which may affect war veterans), dentistry, heart disease and child welfare. Its interest to physicians lies in the information which it contains on the point of view of the American Legion with regard to matters affecting the medical care of veterans. For medical advisers to Legion posts and departments, it constitutes a guide and manual of procedure.

**Atlas of Dermal Pathology.** Prepared [at the Army Institute of Pathology] by the Registry Committee on Dermal Pathology of the American Academy of Dermatology and Syphilology, Hamilton Montgomery, Chairman. Fabrikoid. Price, $5. Pp. 155, with 100 illustrations selected by Arthur C. Allen, Consultant to the Army Institute of Pathology. Registry Press, American Registry of Pathology, under the Auspices of the National Research Council, Army Institute of Pathology, Washington 25, D. C., 1948.

The material in this short atlas has been limited to illustrations of one hundred dermatologic entities with distinctive histologic pictures. They are all photomicrographs in black and white, excellently reproduced on good quality paper. Each illustration is accompanied by a short clinical history and a clear description of the salient features of each section. The book contains an excellent glossary of pathologic terms, a practical classification of the material and references to pertinent literature. Intended, as it is, merely to supplement standard texts on histopathology, the book should be of value particularly to the physician interested in dermatology. Colored illustrations would have added considerably to the value of the book.

**Human Histology: A Guide for Medical Students.** By E. R. A. Cooper, M.D., Reader in Histology, University of Manchester, Manchester, England. With a foreword by F. Wood Jones, F.R.S., F.R.C.S., Sir William Collins, Professor of Human and Comparative Anatomy at the Royal College of Surgeons of England. Second edition. Cloth. Price, 27s. 6d. Pp. 431, with 257 illustrations. H. K. Lewis & Co., Ltd., 136 Gower St., London, W.C. 1, 1948.

Designed to meet British medical examination requirements, this book offers the student a laboratory manual illustrated from the author's teaching collection. Almost all the figures are original photomicrographs of good quality. There are no careful or detailed drawings illustrating cytologic details. The text is similarly elementary, furnishing a brief description of the major morphologic aspects of the tissues with the functional aspects minimized. There are few references to diverging points of view, and the major unresolved problems of histology are avoided. Presumably the results of experimental approaches to histologic problems and the findings of newer technics in microscopy are intended by the author to be covered in collateral lectures, since there are no references to them in the text and the bibliography consists of 20 titles. As a refresher guide for the examinations, the text is a lucidly written compendium, but it is difficult to find a place for it on a reference shelf.

**The Treatment of Malignant Disease by Radium and X-Rays: Being a Practice of Radiotherapy.** By Ralston Paterson, M.C., M.D., F.R.C.S.E., Christie Hospital and Holt Radium Institute, Manchester. Cloth. Price, $11. Pp. 622, with illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1948.

The details of the physics and technical aspects of radiotherapy are clearly described. In attempting to be complete, the author in several instances has discussed in too great detail methods which are cumbersome or are generally accepted as outmoded; this may be confusing to the inexperienced student of radiotherapy. The results of the methods which the author advocates are not presented in this volume. A discussion of the organization and staffing of a tumor institute and a report on the new horizons in radiotherapy are presented. This book is a valuable contribution to the literature on radiotherapy.

# Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

## INDICATIONS FOR CESAREAN SECTION

*To the Editor:*—One of the members of our hospital staff, which is composed entirely of general practitioners, proposed to do a cesarean section on a para VII for the purpose of sterilizing her. Other indications for section were absent. Another physician and I saw the patient as consultants and found no indications for the operation. It was therefore not done. It occurs to me, however, that section for this purpose does not seem too far fetched in this day of antibiotics, blood banks, good laboratory facilities and other modern supportive measures. With these aids it would also seem preferable to do sections rather than difficult forceps deliveries, such as are necessary in some patients with occiput posterior position. Has any authoritative obstetric body recently reviewed the indications for cesarean operations? In our hospital most of us allow the second stage of labor to end spontaneously except for necessary episiotomy or the Ritgen maneuver. What is the common practice in this regard? Does the use of pain-relieving agents (including heavy "nupercaine hydrochloride" spinal anesthesia) make spontaneous delivery increasingly difficult? Is heavy "nupercaine hydrochloride" spinal anesthesia safe for obstetric anesthesia in a small general hospital? M.D., Illinois.

ANSWER.—This letter poses some basic questions which many doctors have thought about. The basic aim in obstetrics is to end up with a whole live mother and a normal healthy baby. One reads of glorious results with this or that analgesic or method of treatment only to find that within a few months the method is forgotten by all, even the authors, but with no retraction in the literature. The lag in publication today is so great that often by the time an article is published, the authors have already stopped using the method.

One should always ask oneself when doing a major procedure, "If the patient should die, would I have been justified in doing the procedure?" This does not mean that all elective surgical treatment should be dispensed with or that women should be allowed to labor with undue odds merely because of operative mortality rates, because sometimes life in these circumstances is worse than death, but it does mean that in spite of modern advances women still die from cesarean section, especially when done by the occasional operator. One cannot compare the mortality figures of a busy obstetrician in a large maternity ward with good anesthetists and blood banks to those of an obstetrician who does one or two sections a year in adverse circumstances. Perhaps, also, one should not use the same criteria for their operative work.

The first question is controversial only in one respect. No one believes in cesarean section for sterilization. The nearest approach is the postpartum sterilization in which the mother is taken to the operating room on the second postpartum day and through a small abdominal incision the tubes are tied. The main reasons offered by the proponents of this method are that the women will not come back for sterilization at a later date. With modern methods of contraception, this should be unnecessary. It is much less hazardous to tie off the vas in the husband than to do a major abdominal operation on the wife. Sterilization in the woman is almost irreversible, even though it fails occasionally, while in the man it can be undone in a fair percentage of cases.

Our criteria for section should be relaxed somewhat. With the advent of roentgenographic pelvimetry, some of the difficult labor experiences would be better terminated by section. Roentgenographic pelvimetry frequently takes all of the fear out of handling occiput posterior positions by indicating in what diameter the head should be brought through.

The sulfonamide drugs and the antibiotics, if used, should be given in sufficient dosage to subdue the infection adequately. If possible, it is better to wait long enough before using them to find out what is causing the fever.

While the trend seems to be toward routine low forceps or outlet forceps or prophylactic forceps deliveries, the difficulty is in determining what is a low forceps delivery. Outlet forceps technics are safe enough so that they should be applied if there is any question about the fetal heart or if the mother has had a long tedious labor.

Apparently no authoritative body has recently reviewed the indications for cesarean section. Such a move is on foot, however, in the question of forceps. Most authors of papers on various types of spinal anesthesia admit that practically all of their cases become operative cases because of the great relaxation caused in the pelvic and perineal structures. This has the effect of increasing the mortality and morbidity statistics in the operative group.

As long as analgesics work as well as they now do, and with local infiltration for episiotomy and inhalation gas anesthesia for delivery, there is no reason to add spinal anesthesia, because it is not without danger, in spite of reports to the contrary.

## PENICILLIN IN NEUROSYPHILIS

*To the Editor:*—What is the effect on: (1) tabes and dementia paralytica of a daily dose of 300,000 units of procaine (crystalline) penicillin G in water to a total of 20,000,000 units; (2) effect of this dosage on penicillin blood levels, and (3) effect of this dosage plus carinamide on penicillin blood levels? M.D., Pennsylvania.

ANSWER.—1. The effectiveness of treatment by daily injections of procaine penicillin in the treatment of dementia paralytica and other forms of syphilis of the central nervous system is under investigation at the present time in several medical centers, but the duration of the studies has not yet been sufficient for reports of results to be made. None of the schedules being tried covers such a long period of time (sixty-six days) as the proposed schedule. So far no penicillin schedules for syphilis of the central nervous system involving relatively continuous penicillin blood levels have been advocated that are longer than twenty-one days. Treatment with penicillin in peanut-oil-beeswax is similar to that with procaine penicillin in that relatively lower and fewer peak levels are obtained than with aqueous solutions of penicillin, although blood levels still go higher initially than with procaine penicillin. The recent report of Parkhurst and Bowman (Treatment of Neurosyphilis at Hot Springs Medical Center, Arkansas, *J. Ven. Dis. Inform.* **29**:159, 1948) indicates that penicillin in peanut-oil-beeswax is effective in the treatment of syphilis of the central nervous system.

2. There is no information in the literature dealing with penicillin blood levels with such a schedule, although with a lesser number (8 to 16) of daily injections of 300,000 units of procaine penicillin average levels would be mainly in the range of 0.08 to 0.64 unit. According to Thomas, Lyons, Romansky, Rein and Kitchen (J. A. M. A. **137**:1517, 1948) sixteen daily injections of 300,000 units of procaine penicillin did not lead to any cumulative effect of penicillin in the blood.

3. Information is not available dealing with the effect of carinamide on penicillin blood levels for this or even shorter procaine penicillin schedules.

## BURNING SENSATION OF TONGUE

*To the Editor:*—A patient, 37 years old, has had good general health. She is high strung and becomes excited easily. Six weeks ago she complained frequently of a burning sensation on the lower lip. This soon involved the tip of the tongue. Her tongue felt as if she had eaten some spicy or hot food. She was not anemic. Examination of the tongue and lips was negative. Thinking that she might have gastric hypoacidity and thiamine deficiency I gave her a prescription containing hydrochloric acid and nicotinic acid. This did not seem to change her complaint. Gastric analysis was essentially normal and did not indicate hypoacidity. Burning sensation now involves the entire tongue, and she feels a hot burning sensation down the pharynx to the esophagus. I have treated her with diphenylhydantoin sodium without results and have also given her bromides for nervousness. She has stopped smoking. I would appreciate suggestions. M.D., Missouri.

ANSWER.—The impression of psychoneurosis is possibly correct, with local irritation of some sort to be ruled out as a cause or associated factor. The bilateral, progressive burning sensation of the lip, tongue and throat, in a nervous woman of 37, in the absence of visible inflammation, anemia or response to therapy suggests an abnormality which may be present in a situational neurosis, menopause, hysteria or phobia.

Infection, gastrointestinal and systemic disorders and allergy seem to be excluded; the site is correct for the last named, but the constancy is against it. Local causes could include an irritant food or beverage, an irritant mouth wash, excessive smoking and new dental work (with a difference of electric potential between dissimilar fillings).

Several measures could be tried after consideration of the previous suggestions. A continued ban on smoking, restriction to bland food and drink; the use of a dilute bland or astringent mouth wash, reassurance, in case of cancerophobia, ½ grain (30 mg.) of phenobarbital three times a day and observation to note an obscure cause are suggested. If the dosage of nicotinic acid was not high, she might be given 100 mg. of nicotinamide orally per day for two weeks. If the burning is associated with dryness, it has been suggested that a trial of neostigmine bromide (7.5 mg. three times a day after meals) will increase the secretions and decrease the burning. If the case seems functional, obtain the help of a neuropsychiatrist.

## TUBERCULOSIS IN IMMIGRANTS

*To the Editor:*—I have seen an impressive number of recent immigrants with far advanced active pulmonary tuberculosis. This would seem to be a valuable and fruitful field for "case finding." What is being done along these lines at the moment?

William A. Evans, M.D., Detroit.

Answer.—This is an exceedingly serious problem which should be solved by all nations. Prior to 1939, Newitt and Koppa observed that each spring several thousand Mexican agricultural laborers (mostly American citizens) journeyed from Texas to work in the sugar beet, onion and peppermint fields of Michigan. These itinerant laborers and their families provided many of the tuberculous persons entering certain sanatoriums in Michigan. In 1937 the roster of the Saginaw County Hospital showed that 25 per cent of the patients were Mexican, the majority of whom had come to Michigan with their families to work as agricultural laborers. This was far out of proportion to their number in the county. A plan was devised whereby sugar beet laborers migrating to Michigan would be examined by the Michigan Department of Health at their concentration headquarters in San Antonio, Texas. In 1939, 4,271 such persons were examined, of whom 81 had tuberculosis, and in 1940, among 5,753 examinees, 121 had this disease. Thus the rejection of these persons for employment prevented an influx into Michigan of a considerable number of cases of tuberculosis.

From Feb. 1, 1943 to Sept. 20, 1945, the Division of Tuberculosis Control and the Foreign Quarantine Division of the United States Public Health Service established an examination center at Mexico City, where laborers were examined prior to entrance into the United States to work under the program of the War Food Administration. A total of 222,156 were examined, of whom 2,313 were rejected. Of these, 1,261 had the reinfection type of tuberculosis, 6 had other forms of tuberculosis, and 1,046 others were classified as tuberculosis suspects. This procedure prevented many with contagious tuberculosis from entering this country.

The importation of tuberculosis through domestic animals has been well controlled in this country. In recent years the U. S. Public Health Service, the immigration authorities and the State Department consular officials have done such excellent work that our citizens should soon be as well protected against tubercle bacilli introduced by persons from other countries as we now are against those imported in cattle. An arrangement was made whereby every person applying for a visa would have roentgen inspection of the chest, and if any shadow was seen the tuberculin test would be administered and a thorough bacteriologic search made when possible. Roentgenograms were made abroad wherever the Public Health Service had medical officers assigned to the consulates and x-ray facilities were available. In the course of medical examinations of visa applicants abroad, those found to have contagious tuberculosis were given class A notifications, and visas were refused.

A person given a diagnosis of pulmonary fibrosis (class B condition) is given a visa and reexamined later on entering the United States.

A provision became effective on Sept. 1, 1948, whereby every applicant for immigration visa will have a roentgen inspection of the chest for tuberculosis and a blood test for syphilis. Those found to have either of these diseases are rejected. (This provision exempts visa applicants 10 years of age or under "unless the examining medical officer has reason to suspect that the applicant has tuberculosis or syphilis.") When examinations are conducted at American consulates which lack x-ray and laboratory facilities the applicant may be required to furnish a roentgenogram of the chest with a reading and a blood serologic report. These and the physical examination records are placed in a separate envelope and attached to the alien's immigration visa for examination by medical officers at the United States ports of entry. If the person originates from a community where there are no facilities for such examinations, the medical officer there so states on the physical examination forms. Those who do not have adequate reports of examination at the port of embarkation are held at the port of entry, pending completion of the examination adequate to determine the presence or absence of tuberculosis or syphilis. Temporary visitors to the United States are excluded from this requirement but may be subject to appropriate examination when tuberculosis or syphilis is suspected.

Since we require such protection for our citizens, we should also afford security to the people of other nations by issuing passports only to those who are adequately examined and found to be free from contagious tuberculosis.

A high percentage of immigrants from some countries are tuberculin reactors without other evidence of tuberculosis. Annual case-finding programs among them are likely to be fruitful.

## VISUAL HALOS

*To the Editor:*—What would cause a "halo" around a bright light? The patient is otherwise apparently in perfect health. Examination of eyes is negative except for a refractive defect. Tension, optic nerve, disk, retina all appear normal. Sight is good, pain is absent and the crystalline lens is normal. The patient is 76 years old and has never been ill. Could a neurosis play any part in his disturbance?

Frank E. Wiedemann, M.D., Terre Haute, Ind.

Answer.—Halos may be caused by a layer of mucus, blood or pus on the cornea, by edema of the deeper layers of the cornea due to glaucoma or inflammation, or by radially arranged fibers in the lens. Those due to secretions on the corneal surface are altered by blinking movements of the lids, which is not true of those due to glaucoma or the lens. Physiologic lenticular halos are distinguished by rotating a stenopaic edge across the pupil. As the different radial fibers of the lens are excluded the halo is partially eclipsed, while those due to secretions appear to revolve around and those due to glaucoma are unchanged or appear fainter. Other differential tests based on measurement of the angular diameter of the halo are discussed in Duke-Elder (Textbook of Ophthalmology, Vol. II, p. 1232, C. V. Mosby Co., St. Louis, 1943.) All tests to eliminate a physiologic cause of the halos must be exhausted before a diagnosis of neurosis is considered. It is most important to eliminate glaucoma as a cause by study of the visual fields; repeated tonometer readings, provocative tests and funduscopy. A halo with an external diameter of more than 17 inches at ten feet not caused by corneal secretion suggests glaucoma.

## SUBDURAL HEMORRHAGE

*To the Editor:*—Please furnish information on occurrence of subdural hemorrhage other than that caused by external force or trauma. Textbooks and the literature fail to give much detail or even adequately discuss this type of hemorrhage. Does it occur as the result of other conditions?

Robert O. Glenn, M.D., Mountain City, Tenn.

Answer.—Subdural hemorrhage rarely occurs except as the result of trauma. In many instances the trauma is relatively slight. True, a number of patients suffering from subdural hematoma also suffer from some disease of the vascular system such as arteriosclerosis, but this of itself is insufficient explanation for the hemorrhage. One of the uncommon causes of subdural hemorrhage without associated trauma is thrombosis of the superior longitudinal sinus either as part of the disease "idiopathic recurrent thrombophlebitis" (Bucy, P. C., and Lesemann, F. J.: J. A. M. A. **119**:402-405, 1942) or from other causes (Courville, C. B., and Nielsen, J. M.: *Arch. Otolaryng.* **19**:483, 1934). Occasional instances of subdural hemorrhage, usually relatively mild, have been reported in association with such diseases of the blood as pernicious anemia, leukemia, polycythemia vera and purpura hemorrhagica. Scurvy has also been cited as a cause, particularly in young children (Govan, C. D., and Walsh, F. B.: *Arch. Ophth.* **37**:701-715, 1947). The possibility of subdural hemorrhage occurring in association with the various acute infectious diseases has also been mentioned, but if this occurs it is extremely rare. Chronic alcoholism and syphilis are usually cited as playing a role in the development of subdural hematomas. At present, practically all authorities agree that when and if these conditions are factors, they are always secondary.

## FLUORIDE IN PREVENTION OF DENTAL CARIES

*To the Editor:*—Fluorides are said in some publications to cause mottling of the dental enamel, and in others sodium fluoride is recommended as a topical application to preserve the enamel. Will you explain these conflicting statements?

Narcisse Francis Theberge, M.D., New Orleans.

Answer.—Mottled enamel, or endemic dental fluorosis, is caused by the continued use of a domestic water containing excessive amounts of fluorides (more than 1.5 parts per million of fluoride) during the period that the permanent teeth are calcifying. With the exception of the third molar this represents about the first eight years of life. This defect is developmental; in a person moving into an endemic area after the permanent teeth have erupted the enamel does not become mottled. Numerous epidemiologic studies attest the quantitative relationship between the use during the susceptible period of a domestic water supply containing excessive amounts of fluorides and the prevalence and severity of the resultant endemic dental fluorosis.

As a result of later epidemiologic studies demonstrating the decided inhibition of dental caries among users of domestic waters containing 1 part per million of fluoride or over, a number of studies have been directed to the utilization of the relationship between fluorine and dental caries for dental control procedures. One of these methods is the topical application of a 2 per cent aqueous solution of sodium fluoride following prophylaxis. Studies completed indicate that after four treatments, spaced about a week apart, a reduction of the order of about 40 per cent may be expected in the incidence of dental caries in the group. Topical application studies so far have been largely limited to children; further studies are needed to determine whether or not it is effective with respect to adults. In teeth treated with topical applications of sodium fluoride solutions the enamel does not become mottled.

The mechanism by means of which fluoride inhibits dental caries is not known. Hodge and Sognnaes (Experimental Caries and a Discussion of the Mechanism of Caries Inhibition by Fluorine, in Dental Caries and Fluorine, American Association for the Advancement of Science, 1946) offer the following hypothesis:

"Fluoride is adsorbed or bound in combination in enamel or in dentin and, probably of most importance, on the surface of the tooth, thereby (1) lowering the solubility of the calcified part; (2) giving a relatively high local concentration of fluoride which inhibits those bacterial or enzymatic processes that otherwise are believed to dissolve the protein and the calcified material; (3) changing the salivary milieu as shown by the L. acidophilus counts. There are probably some systemic actions of fluorides partly responsible for the caries inhibition; these are unknown at present."

## "AGENIZED" FLOUR

**To the Editor:—Are there any known industrial ophthalmic or medical hazards for flour mill workers exposed to the "Agene treatment of flour" using Agenite salts, chlorine and nitrogen trichloride gas? I have an exposed worker as a patient that developed an interstitial keratitis of the right cornea. Wassermann and Kahn are negative (three different laboratories). Tuberculin and Brucella tests were positive. Age, 64 years, male.**

**M.D., Pennsylvania.**

ANSWER.—The "agene" process centers about the action of nitrogen chloride (nitrogen trichloride). This treatment is for the purposes of bleaching and maturing flour and for improving the quality of the bread loaf. In the United States, nitrogen chloride is customarily added in the range between 1.2 to 2.5 Gm. per 100 pounds. At times, ancillary chemicals are utilized for similar purposes, the number including benzoyl peroxide. Provided sufficient exposure, nitrogen chloride gas or chlorine if such be liberated are surface irritants and might induce a conjunctivitis or aggravate corneal ulcers if such exist from other causes. Nitrogen chloride has been found both in this country and in England to provoke convulsive states in laboratory animals, chiefly dogs, after the ingestion of flour products that had been "agenized." No counterpart has been detected in human beings and to a substantial extent this treatment has been held blameless in the causation of any known disturbances in human beings from flour product consumption. However, it is possible that in the flour treating process the exposure to nitrogen chloride may be higher. Notwithstanding, no abnormalities akin to the "running fits" or "canine hysteria" have been reported in workers. Since rarer forms of keratitis have been associated with nutritional disturbances and since neurologic damage is a source of uncommon forms of keratitis, the remote possibility exists that nitrogen chloride may be an influence if adequate exposure has occurred. On the basis of always doubting unusual etiologies in any condition, it is highly probable that the present occurrence of interstitial keratitis may be traced to the usual causes of that state.

## STREPTOMYCIN SENSITIVITY

**To the Editor:—Several nurses who work constantly with streptomycin have become allergic to it and complain about skin manifestations such as eczema, edema and blepharitis. Is there an accepted method of desensitization?**

**Leon A. Alley, M.D., Middleboro, Mass.**

ANSWER.—There is no accepted method of desensitizing persons who are sensitive to streptomycin except avoiding contact with it. Precautions should be taken to avoid contact of the skin with streptomycin. When nurses prepare the solutions, their hands should be protected with rubber gloves. The gloves should be washed carefully before they are removed and every precaution should be taken to prevent streptomycin from coming in contact with the skin or conjunctivae.

## IMPOTENCE IN DIABETES

**To the Editor:—A 37 year old patient has diabetes well controlled by diet and 32 units of protamine zinc insulin daily. He complains of impotence, which seems to be increasing in severity despite the fact that he married only a short time ago, after finding that he had diabetes. Is there any treatment for this condition?**

**James E. O'Malley, M.D., Anchorage, Alaska.**

ANSWER.—Impotence in diabetes is a symptom which is not completely understood. It is thought to occur more frequently in cases in which neuritis is associated with diabetes than with any other form, possibly because of changes in the nervi erigentes. Impotence is likely to develop in men who have had diabetes for long periods; a third possible factor is a lowered production of androgens as reflected by a diminished excretion of 17-ketosteroids. Miller and Mason (*J. Clin. Endocrinol.* **5**: 220-225 [May-June] 1945) found that a majority of impotent diabetic men excreted less than normal amounts of 17-ketosteroids; on the other hand, a significant number of diabetic men who did not complain of impotence also excreted subnormal amounts of 17-ketosteroids. Psychologic factors constitute a fourth and important possibility. Such factors could well be the cause of impotence in the case in question, particularly since the patient has had diabetes only a short while and no mention was made of the presence of neuritis.

As far as treatment is concerned, if impotence is the result of neuritic lesions, careful control of diabetes for months and even years offers a chance for the return of potency. Because of the diminished excretion of 17-ketosteroids in diabetes, a trial of testosterone propionate (25 mg. intramuscularly three times weekly) seems justified. Treatment with androgen should not be expected to have an effect on a neuritic process, and has not been helpful in many cases of impotence. An investigation of psychic factors is also indicated. This approach is set forth well on page 361 of the textbook "Psychosomatic Medicine," by Weiss and English.

## TREATMENT OF WARTS

**To the Editor:—Where can I obtain a verruca vaccine or filtrate? I have 2 patients with multiple recurring verrucae on the face, dating from five years in one. I have tried superficial roentgen treatment, local medication and dessication. The lesions continue to recur.**

**Albert Rubin, M.D., Hartford, Conn.**

ANSWER.—Apparently verruca extract, a vaccine or filtrate, cannot be obtained commercially. It must be processed as described in the article by Hans Biberstein (Immunization Therapy of Warts, *Arch. Dermat. & Syph.* **50**:12-22 [July] 1944). Recurrent warts on the bearded area have always plagued dermatologists. If they continue to reappear despite persistent treatment by various means such as destructive measures, treatment with arsenicals, mercury, roentgen therapy and exfoliating preparations, one might resort to hypnosis by an expert psychotherapist.

## ERYTHEMA NODOSUM

**To the Editor:—A case of mediastinal adenopathy with erythema nodosum (proved by biopsy and clinical course) poses the following problems: (a) incidence and most likely tumor and disease of the mediastinum with erythema nodosum, and (b) incidence of erythema nodosum with Boeck sarcoid if any. The patient, a woman aged 33, began having a pain in the right side of the chest several months ago, and still has it. The pain is worse on inspiration and in the upright position. She has had a poor appetite for years. Except for total proteins of 5.8 Gm. per hundred cubic centimeters, with normal albumin-globulin ratio and slight hypochromic anemia, significant findings are lacking.**

**Anthony M. Susinno, M.D., Palisades Park, N. J.**

ANSWER.—The presence of mediastinal adenopathy should suggest first the presence of pulmonary tuberculosis, but it occurs also in brucellosis, mycoses, Hodgkin's disease, neoplasm, and in about any disease affecting the lungs. Its occurrence with erythema nodosum should suggest also the presence of a focus of tuberculosis as the primary possibility, particularly in a young woman. Erythema nodosum, however, as a pattern reaction, may accompany any infectious process, and its occurrence with sarcoidosis has been noted. The incidence of erythema nodosum, aside from that due to drugs, is not high in this country, and its occurrence with sarcoidosis is even rarer.

## DIETHYLSTILBESTROL IN VARICOSITIES

**To the Editor:—Is diethylstilbestrol a valuable factor in alleviating pain of varicose veins in pregnancy?**

**Kurt Oppenheimer, M.D., Norwich, Conn.**

ANSWER.—Reliable evidence that diethylstilbestrol relieves the pain associated with varicose veins during pregnancy is lacking.

## PROMINENT FACIAL VEINS

*To the Editor:*—What can be done for a patient who is sensitive regarding a prominent superficial vein on the left frontal region which under certain circumstances becomes noticeable. She wants this vein ligated under the hair of the temporal region so that the scar will be covered. Can harm result from such a procedure?

*Mario Camarena, M.D., Mexico.*

Answer.—Ligation of short venous segments for cosmetic reasons seldom if ever results in satisfaction for the patient or the surgeon. In the first place, the venous dilatation may readily recur if it is the result of increased venous pressure due to some mechanical obstruction; secondly, the undermined skin may develop a subcutaneous scarring and pigmentation which is more noticeable than the original lesion. Certainly the decision should be made by a plastic surgeon after a personal examination of the patient. If the lesion is part of a congenital vascular anomaly and seems to enlarge, then a combination of sclerosing therapy and surgical incision is warranted. Cosmetic preparations often help to cover the lesion.

## INFANTILE MAMMARY ENLARGEMENT

*To the Editor:*—A 1 year old girl has a slightly enlarged left breast. The tissue feels somewhat firm, not nodular, but is more like an excess of normal glandular tissue. The left breast is about twice as large as the right. Since first noticed six months ago, it has grown only in proportion with the rest of the body.

*M.D., Mexico.*

Answer.—It is not unusual to find an enlargement of the mammary gland substance in infants, which is usually unilateral, smooth and hard, averaging about the size of a 25 cent piece. While a difference in size of the breasts may continue, they usually become more equal in size as the breasts develop toward puberty. Those that are smooth and contain no nodules should cause no apprehension as to malignancy. They may originate from slight mastitis during the early days of life.

Several years ago some foreign writers stressed the influence of the hormones of pregnancy on the enlargement and secretory function of the breasts of newborn babies.

## MUSCULAR DYSTROPHY

*To the Editor:*—Are there recent developments of value in treatment of pseudohypertrophic muscular dystrophy?

*Harry Winkler, M.D., Charlotte, N. C.*

Answer.—Pseudohypertrophic muscular dystrophy is not influenced by any known therapy, though good claims have been made for glycine and vitamin E. Recent carefully controlled studies demonstrate that glycine and vitamin E have not been of value. One should keep the dystrophic patient ambulant and postpone ultimate confinement to bed as long as possible. Massage may be tried but electrotherapy should not be used.

## BLADDER STONE

*To the Editor:*—Is there anything unusual in the spontaneous passage by a female of a bladder stone of elliptical shape which is 2 inches (5.1 cm.) in length and 1½ inches (3.8 cm.) in breadth?

*M.D., Virginia.*

Answer.—The spontaneous passage of a bladder stone of the described size is unusual. The female urethra is capable of wide dilation but normally can only be stretched to 35 F, which would be 105 mm. in diameter. In the case of a stone 1½ inches in diameter the dilation would be about four times what normally could be effected by the instrumental dilation.

## AMEBIASIS

*To the Editor:*—In 1939 a white girl, aged 5, had amebic dysentery in Nassau, Bahama Islands. She was treated with arsenical preparations. In 1940 two stool examinations at six month intervals were negative for Endamoeba histolytica. She is now a well developed and well nourished girl. In September her mother noticed a peculiar odor to her stools. A laboratory examination disclosed Endamoeba histolytica. She has no other symptoms. What are the treatment and prognosis?

*M.D., New Jersey.*

Answer.—All carriers of Endamoeba histolytica should receive treatment starting with a drug of low toxicity; chiniofon, containing 26 to 28 per cent iodine, is such a drug. It is available in 0.25 Gm. tablets. Three tablets may be given orally after each meal for eight to 10 days. The dose may be reduced if diarrhea occurs. The course of treatment may be repeated in ten days. There need be no limitation of the patient's activity. In older children diiodo-oxyquinoline may be used in an oral dose of two 0.21 Gm. tablets three times a day for twenty days. If the iodine-containing drugs are not successful carbarsone may be used in an oral dose of 0.25 Gm. twice daily after meals for ten days. Stools should be examined once a month for at least three months after treatment. Under modern treatment most amebic carriers are curable.

## SULFONAMIDE DOSAGE

*To the Editor:*—Colleagues prescribe sulfonamide drugs and then cut the dose down or prolong time interval between doses as patient improves. Is it better to maintain therapeutic dosage until cure is established and then stop drug entirely? What is the latest opinion about iron administration to premature infants?

*Harry W. Orris, M.D., Lynn, Mass.*

Answer.—Absolute rules concerning the precise method of administering sulfonamide drugs to patients with infections do not exist. In general, it can be said that dosage schedules and duration of treatment must be determined on a basis of the type and location of infection and the response to treatment. It is a common practice to maintain therapeutic doses until the patient has recovered and then stop the drug entirely. If relapse occurs, the drug can be started once again.

The use of iron preparations for the treatment of anemia that occurs in infants that have been born prematurely is recommended.

## VASECTOMY

*To the Editor:*—Should partial vasectomy for birth control be advised for a patient under age of thirty-five? Is it advisable at all? After this operation the libido of the person is increased for a period of eight to ten years, then it decreases to practical absence and remains at that level. I have advised against vasectomy under age fifty but my colleagues do it and tell me that I am wrong. Please advise me on this matter.

*O. E. Layton, M.D., Collinsville, Okla.*

Answer.—There is some difference of opinion among urologists concerning vasectomy for birth control. However, the present consensus seems to be that it should not be done. Conclusive evidence that vasectomy has any effect whatsoever on the individual's sexual life is lacking except that he becomes azoospermic. Vasectomy is indicated and is done for the prevention of epididymitis following prostatic operations and also in some instances to prevent recurrent attacks of epididymitis.

## DETERMINING THE SEX OF CHICKS

*To the Editor:*—Please give information on methods used by the Japanese in determining the sex of chicks.

*Stuart B. Blakely, M.D., Binghamton, N. Y.*

Answer.—The Japanese method of sexing chicks within one day of hatching depends on recognition of minute differences in the configuration of the rim of the cloacal orifice; a small rounded protuberance in males is the diagnostic feature. There is considerable, although minute, variability in the topography of this region and the method has to be "learned" and practice is required. An expert attains approximately 98 per cent perfection. *The American Scientist*, April, 1948, page 280, carried an excellent article on this "art."

## HISTAMINE IN GASTRIC ANALYSIS

*To the Editor:*—The answer to the query "Histamine in Gastric Analysis" in The Journal, September 18, page 256 is incomplete. It states, "The usual dose of 0.1 mg. histamine base for each 10 kilograms of body weight may perhaps be a little high. . . . Satisfactory results can be obtained by using 0.3 to 0.5 mg of histamine base."

The only occasion for the use of histamine in gastric analysis for diagnostic purposes is when the basal gastric contents do not contain free hydrochloric acid and one wishes to know whether the patient's stomach is capable of secreting hydrochloric acid. This information may have crucial diagnostic significance. Under these circumstances the dose of histamine should be one which is greater than that needed to evoke a maximal secretory response in the average normal person. Actually, there are no data on the dose of histamine required to produce a maximal response in normal subjects, and this problem deserves study. Until such information is available, in testing persons to determine whether their stomach is capable of secreting hydrochloric acid one should use as large a dose of histamine as can be tolerated without untoward effects, and 0.1 mg. histamine base per 10 kilograms of body weight is a satisfactory empiric figure for this purpose. Any any rate, no reduction in dosage should be advised. Even at this dosage level it is sometimes necessary to do repeated tests to elicit acid secretion in refractory cases.

## THE TREATMENT OF ACUTE PERITONITIS

W. A. ALTEMEIER, M.D.
Cincinnati

During the phenomenal development of chemotherapy in the past thirteen years, considerable confusion has arisen regarding the value of the various agents in the management of acute septic peritonitis. Although most surgeons agree that chemotherapy has been of great value, there is no agreement as to which is the best agent to use or what is the best manner of its application. A summary of the present knowledge and experience is presented to establish the relative place of chemotherapy, the most effective agents and any changes in surgical practice made possible in the management of acute septic peritonitis.

There is still no specific treatment for acute septic peritonitis, and successful management is dependent primarily on good surgical intervention, aided by early and correct diagnosis, chemotherapy and adequate preoperative and postoperative care.

*Early Correct Diagnosis.*—When peritonitis exists, the earlier the diagnosis is made, the more effective is prompt treatment. A determination of the type of peritonitis as well as the exciting etiologic factor which precipitated the infection is necessary for intelligent and definitive operative treatment. Acute septic peritonitis may occur as one of two general clinical types: a primary type, usually occurring in children and having a monomicrobic causation, the etiologic factor being the pneumococcus or a hemolytic streptococcus, and a secondary type, having a polymicrobic [1] and nonspecific causation and arising from perforation or leakage of the intra-abdominal viscera. The most important sources of secondary peritonitis are inflammations and injuries of the gastrointestinal tract, and the commonest factor is acute appendicitis. Other important gastrointestinal causes include spontaneous perforation of a peptic ulcer or traumatic perforation of the stomach or intestine. Acute cholecystitis, acute pancreatitis, acute diverticulitis, areas of necrosis due to volvulus, strangulation or intussusception of the bowel and, occasionally, sloughing of a malignant tumor may be precipitating factors. Disease or injury of the female genital tract, including septic abortion, puerperal sepsis, gonorrheal salpingitis, trauma during parturition, curettage, induced abortion and, occasionally, spontaneous rupture of a tubo-ovarian abscess, may also be a source of peritonitis. Lesions of the urinary tract are less important causes. Postoperative peritonitis may be the result of continued leakage from a gastrointestinal perforation or a faulty suture line of an anastomosis, continuation of the infection for which the operation was originally done, operative contamination of the peritoneum or of sponges or other foreign bodies left in the peritoneal cavity. Penetrating wounds of the abdominal wall without perforation of an intra-abdominal viscus are not important sources of peritonitis.

It is particularly important to determine whether or not progressive leakage from a perforated viscus is present in peritoneal infections secondary to inflammations or injuries of the gastrointestinal tract other than acute appendicitis. The demonstration of gas in the peritoneal cavity by decreased hepatic dulness on percussion or by a roentgenogram of the upper abdomen with the patient in the upright or lateral decubitus position will help to establish the presence of such a perforation. The necessity of accurate determination not only of the location, extent and severity of the peritonitis but also of the organ primarily involved is obvious for the correct placement of the surgical incision and the institution of intelligent supportive therapy.

### OPERATIVE TREATMENT

Since the great majority of the cases of acute septic peritonitis is secondary to lesions of the alimentary tract, the treatment is still primarily surgical. It has been the policy of surgeons at the Cincinnati General Hospital to operate promptly in most instances, removing the focus of infection or closing the gastrointestinal perforation with a minimum of trauma, as soon as the patient's condition permitted. The logic of early operation to prevent further and general peritoneal contamination is obvious, and the results of surgical intervention before abdominal distention and intestinal stasis have developed have been very satisfactory. In civilian practice, each perforation should be closed, and most perforations can be repaired by inverting Lembert or mattress sutures of medium or fine black silk. When resection is necessary, primary anastomosis by the closed end to end method is preferred at the Cincinnati General Hospital, although we do not hesitate to make a proximal colostomy in rectal or low sigmoidal injuries or to exteriorize extensively damaged segments of colon.

Unfortunately opinion differs among surgeons concerning the operative and nonoperative treatment [2] of

established and spreading peritonitis, but it is our belief that surgical judgment of the individual case should take precedence over any fixed rule. In the cases where the patients show little or no signs of abdominal distention, falling blood pressure and cyanosis, immediate operation has been generally practiced at our clinic regardless of the duration of the infection and as soon as the diagnosis has been made and the chemical alterations of the blood corrected (table 2).

            - (*d*) Operative contamination of the peritoneum
        - 2. Perforating wounds of abdominal wall only

However, in the neglected or moribund patients with marked distention, dehydration and cardiovascular depression, surgery has been postponed and conservative therapy used until localization or improvement might occur. In a total of 258 patients with cases of complicated acute appendicitis, 167 with peritonitis and 53 with appendical abscess, which were treated between January 1942 and April 1, 1948, 248 were operated on, and only 10 were not. Of those treated nonoperatively, 4 were moribund on admission and died within twelve hours of admission. The remaining 6 had cases with abscess in which the infection subsided during conservative therapy. There was a general mortality of 6.2 per cent and a postoperative mortality of 4.8 per cent for the entire series. Likewise, in a series of 179 consecutive cases of perforated peptic ulcers with peritonitis, treated in the same period, 169 patients underwent operation with closure of the perfoation, and 10 did not, because of their moribund state in 8 instances and the prolonged period of elapsed time since perforation in 2 cases. All 8 of the patients with neglected cases died shortly after admission. The general mortality was 11.7 per cent, while the postoperative mortality was 7.6 per cent.

Patients with appendical abscesses generally have been treated conservatively to permit their infections to subside spontaneously if possible. However, if the size of the abscess or the signs of infection did not begin to diminish within twenty-four to forty-eight hours or if the signs increased at any time, immediate plans for operation were made. In 53 cases of abscess, 45 patients were operated on within twenty days after admission, and 13 were treated by incision and drainage without appendectomy. The mortality among the 13 treated with incision and drainage only was 15.3 per cent, and that among the 35 undergoing appendectomy with drainage was 5.7 per cent. Intra-abdominal abscesses other than appendical ones have been incised and drained as soon as their presence has been determined and localization has occurred.

In making abdominal incisions for peritonitis, it is important for one not to dissect back the various layers any more than is absolutely necessary since doing so exposes greater areas of areolar tissue, which have little resistance to contamination and infection by the mixture of bacteria in the peritoneal exudate.[2a]

There is a growing belief that it is unnecessary and useless to attempt to drain the peritoneal cavity in the presence of diffuse contamination or diffuse peritonitis. This belief is particularly true in the treatment of perforated peptic ulcers and penetrating wounds of the abdomen. Drainage of the peritoneal cavity was not employed in a single instance in the 169 cases of perforated peptic ulcers and in only 4 instances in 156 cases of patients undergoing operation for penetrating wounds of the abdomen. However, if the retroperitoneal tissues were found to be contaminated, it was considered necessary to drain them through a stab wound in the flank.[3]

In established peritonitis arising from appendicitis and other lesions of the gastrointestinal and genitourinary tracts, the question of drainage is decided on the merits of each individual case. Careful removal of excessive exudate by suction has been done as part of the operation, but extended efforts to cleanse the peritoneal surfaces have not, since they disturb natural protective mechanisms of the peritoneum. Only the

TABLE 2.—*Incidence and Mortality of Three Types of Peritonitis*

| Type of Peritonitis | No. of Cases | Surgical Treatment | Nonoperative Treatment | Total Mortality | Postoperative Mortality |
|---|---|---|---|---|---|
| Appendical peritonitis or abscess | 258 | 248 | 10 | 6.2% | 4.8% |
| Perforated peptic ulcer | 179 | 169 | 10 | 11.7% | 7.6% |
| Penetrating wounds of the abdomen | 161 | 156 | 5 | 14.2% | 11.5% |
| Total | 598 | 573 | 25 | | |

TABLE 3.—*Intraperitoneal Drainage in Operative Cases of Peritonitis*

| Type of Peritonitis | No. of Operative Cases | No. Treated with Drainage |

presence of foreign bodies, necrotic tissue, or localized collections of pus has been considered an indication for drainage.[4] As in the past,[5] the incidence of postoperative pelvic abscess in the patients treated by appendectomy with drainage of the peritoneal cavity was one-half that in the patients treated without drainage.

TABLE 4.—*Comparison of the Incidence of the Causes of Death in Penetrating Wounds of the Abdomen Before and After Chemotherapy*

| 104 Cases Admitted Between January 1938 and January 1942 | | 161 Cases Admitted Between January 1942 and May 1948 | |
|---|---|---|---|
| Cause of Death | No. of Cases | Cause of Death | No. of Cases |
| Peritonitis | 9 (31.0%) | Hemorrhage | 7 (30.4%) |
| Hemorrhage | 7 (24.1%) | Pneumonia | 4 (17.4%) |
| Shock | 6 (21.3%) | Putrefactive empyema | 4 (17.4%) |
| Pneumonia | 5 (17.2%) | Peritonitis | 2 ( 8.7%) |
| Uremia | 1 ( 3.4%) | Meningitis | 2 ( 8.7%) |
| Retroperitoneal cellulitis | 1 ( 3.4%) | Uremia | 1 ( 4.3%) |
| | | Undetermined | 1 ( 4.3%) |

TABLE 5.—*A Comparison of the Mortality of Three Types of Peritonitis Before and After Adoption of Chemotherapy*

| | Cases Treated Without | | Cases Treated with | |
|---|---|---|---|---|
| Type of Peritonitis | Chemotherapy | Mortality | Chemotherapy | Mortality |
| Appendical peritonitis or abscess | 338 | 14.6% | 244 | 4.9% |
| Perforated peptic ulcer | 143 | 26.6% | 160 | 9.3% |
| Penetrating wounds of the abdomen | 104 | 27.9% | 161 | 11.5% |

In the 204 cases with peritoneal drainage, the mortality was 5.4 per cent, whereas there was no mortality in 46 cases treated without peritoneal drainage. The low mortality in the latter group may not be significant and only the result of a definite tendency to drain only the severer infections. The very indications for drainage used at this clinic are not only evidences of a severer infection but also potent factors for the enhancement of bacterial[6] virulence. When drains are used, they are of the Penrose type, which are placed near the original source of the infection and in some instances into the depth of the pelvis and along the right paracolic gutter, the two areas where purulent fluid is prone to collect.

## CHEMOTHERAPY

During the past ten years the mortality of septic peritonitis has been progressively diminished, and part of the reduction undoubtedly has been due to the introduction and general use of effective antibacterial agents. The mortality of primary or idiopathic peritonitis caused by the pneumococcus or beta hemolytic streptococcus has been reduced from 70 up to 90 per cent to 30 per cent or less by surgical drainage and adequate chemotherapy.[8]

Significant decreases in the mortality of secondary peritonitis have also been striking. In a recent analysis[3] of 161 consecutive cases of penetrating wounds of the abdomen or chest and abdomen occurring at the Cincinnati General Hospital between January 1942 and May 1946, it was found that the mortality was only 11.6 per cent, and peritonitis was a cause of death in only 2 cases, the infection having followed continued leakage from an overlooked perforation or insecure anastomosis.

In contrast, 104 cases of penetrating wounds of the abdomen treated without chemotherapy in the preceding four years showed a mortality of 27.9 per cent with generalized peritonitis responsible for 31 per cent of the deaths. Our experience since 1946 with penicillin used alone or with sulfadiazine has continued to be good, with extremely effective control of the severe contamination and the elimination of peritonitis and severe infections of wounds as causes of death except in those instances in which a perforation was unnoticed or a suture line of an anastomosis leaked.

In a similar manner, the general mortality in 160 cases of patients with perforated peptic ulcers which were treated with sulfadiazine and/or penicillin, including the moribund patients who died shortly after admission, was 9.3 per cent, compared with 26.6 per cent in 143 earlier cases treated with chemotherapy (fig. 1). When penicillin and sulfadiazine were used, the average postoperative febrile period was only 6.3 days, whereas it was 8.0 days when penicillin alone was used and 12.4 days when only sulfadiazine was given.

In peritonitis or an abscess secondary to appendicitis the general mortality has been reduced from 14.5 per cent in 338 cases treated without chemotherapy between 1934 and 1938[5] to 4.9 per cent in 244 cases treated with chemotherapy between 1942 and 1948. The average duration of the infection in the later group was 3.8 days. The results were definitely superior in those cases treated with a combination of penicillin and sulfadiazine, not only with respect to mortality but also in regard to the morbidity and incidence of secondary intra-abdominal or wound abscesses (fig. 2).

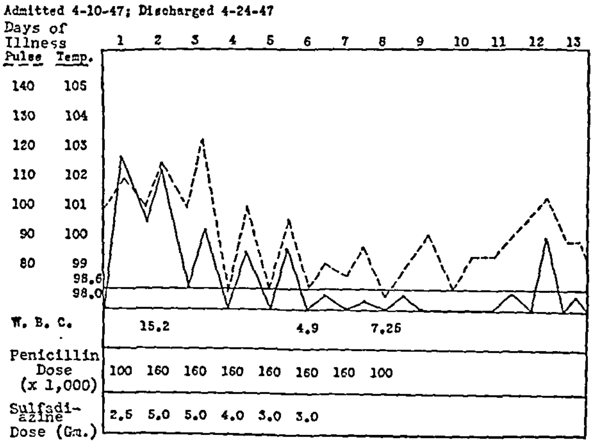

FIG. 1.—Clinical course with a typical response to operation and combined chemotherapy with penicillin and sulfadiazine in a case of perforated peptic ulcer with peritonitis.

There were no deaths in the 63 cases treated with penicillin and sulfadiazine nor in the 11 cases treated with penicillin, sulfadiazine and streptomycin. On the basis of our clinical experience, we recommend the following chemotherapy for effective treatment of acute secondary peritonitis: the parenteral administration of penicillin and sulfadiazine, the combined use of penicillin, streptomycin and sulfadiazine or the injection of large doses of penicillin. When several drugs are used in combination, the dose of each agent should be therapeutically effective. The dosage of penicillin when it is used singly is a minimum of 100,000 units given at intervals of two or three hours. In severe infections, it is our practice to revise this dosage upward, giving as high as 500,000 or more units every two or three hours. Intraperitoneal instillations of any of the agents are not used.

Originally it was thought that penicillin would be of little or no value in the prevention or treatment of secondary peritonitis because a large proportion of the infecting bacteria were of the gram-negative variety, which were either naturally resistant to the action of penicillin or were producers of enzymes which inhibited or destroyed the action of penicillin.[10] The experience of Crile,[11] Brown,[12] Pulaski and associates,[13] Blain[14] and Silvani and associates,[15] as well as ours, however, has indicated that these theoretical objections are not valid and that in reality penicillin in large dosage is probably the most effective single agent available in the treatment of peritonitis today.

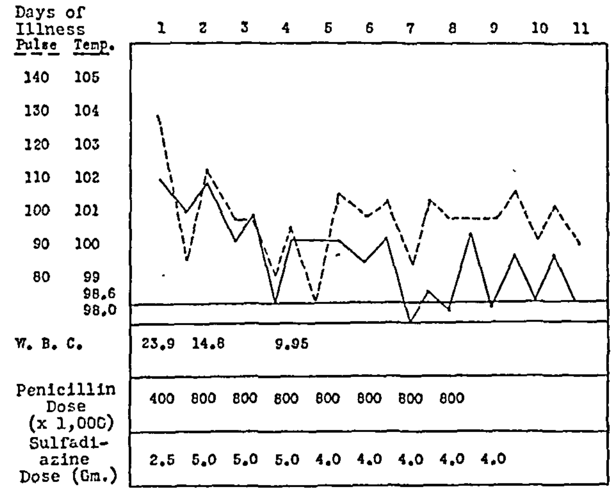

Fig. 2.—Clinical course with appendectomy and combined penicillin and sulfadiazine therapy in a young woman with acute perforated appendicitis and generalized peritonitis of 4.5 days' duration.

A review of our previous experimental work in peritonitis[16] suggests the explanations for the clinical effectiveness of penicillin. The bacterial flora of the peritoneal exudates was found to be mixed and varied in a study of 100 perforated appendixes, 3 or more species of bacteria being recovered from 96 of the 100 cases and as many as 7 types being occasionally isolated. Among the aerobes recovered were Escherichia coli, streptococci, Corynebacterium pseudodiphthericum, staphylococci, Aerobacter aerogenes, Proteus vulgaris, Alcaligenes faecalis, Bacillus subtilis and Bacillus mesentericus; and among the anaerobes were Hemophilus melaninogenicus, streptococci, gram-negative diplococci. Bacteroides funduliformis, Bacteroides fragilis and members of the Clostridium group. A further study[17] of the pathogenicity of these bacteria in pure and mixed culture revealed that the majority of the strains tested, particularly those of the gram-negative aerobic bacteria, possessed very small or no native invasive qualities. When injected subcutaneously they produced only minor local lesions or cellulitis and failed to cause a fatal peritonitis when injected intraperitoneally. Of 21 strains of Esch. coli tested, only 3 were found to be virulent, while the low virulence of the remaining 18 was surprising. In the same manner the majority of the anaerobic bacteria investigated, with the exception of the hemolytic streptococci, B. funduliformis, B. fragilis and the clostridia, did not produce fatal peritonitis. However, if several or more strains of these bacteria were mixed and injected intraperitoneally or subcutaneously, their composite virulence was tremendously increased, and their synergistic effect was repeatedly demonstrated by the production of extensive areas of cutaneous cellulitis with gangrene or overwhelmingly fatal peritonitis. Three things were concluded: that secondary peritonitis is essentially a synergistic infection produced by the accumulative action of the various bacteria; that nonpathogenic micro-organisms may play an important part by increasing the virulence of others with which they are associated, and that the pathogenicity assigned to Esch. coli and other gram-negative aerobic bacilli by some investigators is greatly exaggerated, the frequent ascription of peritonitis to the unaided activity of Esch. coli being without sufficient justification.

Many of the gram-positive cocci and bacilli which are associated with peritonitis are susceptible to the action of penicillin. By giving large doses of penicillin, one produces a concentration sufficient to inhibit the growth of the virulent gram-positive bacteria, particularly the anaerobes, thereby reducing the number of organisms growing actively in the peritoneal exudate and lessening the synergistic effect ordinarily produced. Although the growth of the gram-negative bacilli is not checked, the infection is controlled by the normal defensive mechanisms of the peritoneum. This observation supports our previous findings that Esch. coli is not a truly pathogenic organism in the majority of instances, but in reality is a saprophyte. In addition, the diminished incidence of necrotizing infections and cellulitis in wounds of patients receiving large doses of penicillin indicates that Esch. coli is not a chief offender when growing in the absence of the gram-positive aerobes and anaerobes.

### SULFONAMIDE DRUGS

Systemically administered sulfadiazine or sulfamerazine is a valuable adjunct in the therapy of peritonitis.[18] Its action depends not only on bacteriostasis of the susceptible bacteria but also on a nonspecific protection against the lethal effects of bacterial toxins.[19] In our experience, the results of sulfonamide therapy are enhanced considerably if the sulfonamide drug is combined with penicillin.

### STREPTOMYCIN

The available clinical experience and experimental studies indicate that streptomycin is not as effective as penicillin. The studies of Zintel [20] and Silvani and his associates [15] showed that the therapeutic results of streptomycin in experimental peritonitis in dogs were not as good as those of penicillin or a combination of penicillin and sulfadiazine. The clinical experience of Hirshfeld and his associates [21] and Pulaski, Seeley and Matthews [13] with peritonitis of various causations agrees with ours in that streptomycin appeared to be of greatest value in the treatment of early spreading peritonitis but that it was of questionable value in localized peritoneal suppuration or severe established peritonitis. Because of streptomycin's inability to control the important anaerobic cocci and bacilli of peritonitis, we no longer use it alone, but employ it only in conjunction with penicillin or sulfadiazine. In some instances it has been effective in combination with penicillin and sulfadiazine in infections which have failed to respond to penicillin alone or to penicillin and sulfadiazine.

### SUPPORTIVE THERAPY

Preoperative and postoperative preparation should be directed toward the correction of the derangements in physiologic chemistry caused by the peritoneal infection and the resultant toxemia. The important aspects of adequate supportive therapy include the correction of disturbances in water and electrolyte balance, of protein depletion and of vitamin deficiencies, as well as the use of gastrointestinal decompression, Fowler's position and oxygen therapy. It is not within the scope of this paper to elaborate on these subjects.

### SUMMARY

A review of our clinical experience during the past six years with 598 cases of acute septic peritonitis secondary to acute appendicitis, perforated peptic ulcers and penetrating wounds of the abdomen indictes that successful management depends primarily on early diagnosis and good surgical intervention and secondarily on chemotherapy and adequate supportive treatment. There is no specific therapy for this infection as yet, and chemotherapy is not a substitute for prompt diagnosis and early operative repair or removal of the primary source of infection before abdominal distention, intestinal stasis and cardiovascular depression have occurred.

A comparison of the results obtained in 685 similar cases treated without chemotherapy with those in cases in which chemotherapy was used reveals that the mortality has been reduced approximately 60 per cent recently and that this reduction is apparently due to the effects of chemotherapy.

The most effective chemotherapy in our experience is obtained by the combined parenteral administration of sulfadiazine and penicillin or that of penicillin, sulfadiazine, and streptomycin. When used alone in a high dosage of 100,000 to 500,000 units every two or three hours, penicillin is effective in the great majority of instances, with the exception of those infections caused in part by virulent gram-negative bacteria.

A review of our previous experimental work suggests that the unexpected effectiveness of penicillin in acute septic peritonitis is the result of a conversion of a severe synergistic and mixed infection into a simpler one produced predominantly by gram-negative bacteria, usually of low virulence. The combined use of sulfadiazine and/or streptomycin with penicillin is recommended for the further control of this etiologic component of peritonitis.

Cincinnati General Hospital.

## ABSTRACT OF DISCUSSION

Dr. Champ Lyons, New Orleans: I like to urge a continuation of surgical aggressiveness in the management of peritonitis. Fecal peritonitis, in contradistinction to primary peritonitis, is always secondary to the injury of tissue within the peritoneal cavity. The initiating factor in fecal peritonitis is the injury of tissue, due to trauma, infarction or escape of digestive enzymes or succus entericus. The devitalized tissue and accompanying serous exudate offer a ready pabulum for the growth of bacterial contaminants from the gastrointestinal tract. The challenge to antibacterial therapy is, therefore, twofold: first, to control the spread of the infection from the original nidus, and, second, to sterilize the devitalized tissue. The vast numbers of organisms present in peritonitis favor the survival of a minimal infective dose of primarily resistant variants. It follows, then, that an effort must be made to use an agent or agents capable of affecting all of the organisms involved. Clinical experience with purified penicillin G, the presently available product, has led me to believe it is far less potent than the older mixture of many amorphous penicillins and potentiating impurities. We have heard the evidence for the antibacterial effect of penicillin on gram-negative bacilli when that drug is used in synergism with streptomycin and sulfadiazine. Of perhaps greater importance is the effect of the three drugs together in preventing the emergence of penicillin-resistant strains of gram-positive bacteria when large numbers of bacteria are present in the original inoculum. Our clinical experience has validated the concept that the treatment should consist of independently optimal dosage of each of the three drugs. We have found this dosage to be 1,500,000 units of penicillin G, 0.75 to 1.5 Gm. of streptomycin and enough sulfadiazine per day to maintain a blood level of 5 mg. per hundred cubic centimeters. The antibiotics may be given at intervals of eight hours without apparent disadvantage. The development of residual abscesses, long thought to be evidence of inadequate antibacterial effect, is open to an entirely different interpretation. It is now recognized that no antibacterial agent can prevent the ultimate septic decomposition of contaminated and completely devitalized tissue. Viewed in this light, residual abscesses may be held to reflect the incidence of tissue infarction prior to control of the infection. Suffice it to say here that the peripheral circulatory collapse associated with the toxemia of peritonitis is also responsive to blood transfusions when combined with surgical correction of certain lesions.

*Major Edwin J. Pulaski*, Fort Sam Houston, Texas: Analysis of 102 cases of peritonitis of fecal origin treated in United States Army hospitals revealed the following: 1. Of 26 patients given streptomycin alone, intramuscularly in average doses of 2.5 Gm. a day for from five to nine days, 50 per cent were regarded as definitely benefited. Beneficial results were obtained in early spreading peritonitis. On the other hand, this drug did not seem to have an influence on strikingly localized peritoneal infection. 2. Of 76 patients given adjuvant streptomycin in combination with penicillin, with sulfadiazine added in 17 cases, 80 per cent were considered definitely benefited. Localizing infections seemed to resolve more rapidly with the combination than when streptomycin was employed alone. The substantial improvement of the results in *comparison with those of the streptomycin series is attributed to* the addition of penicillin to the streptomycin therapy program. These results are essentially in agreement with those presented by Dr. Altemeier. Bacteriologic evidence has been accumulated, validating the clinical use of combinations of streptomycin, penicillin and the sulfonamide drugs in properly selected cases. We have confirmed the observations of others that combinations of these three antimicrobial agents are optimally antibacterial for Staphylococcus aureus and Streptococcus hemolyticus. In vitro tests with the triple combination against the gram-negative bacteria Escherichia coli, Proteus vulgaris and Pseudomonas aeruginosa showed that the amount of each drug required in the combination was significantly less than that needed when any one drug was employed alone. Furthermore, the tests revealed that the rate of emergence of streptomycin-resistant strains was delayed in all instances. These studies are not meant to suggest economy by the reduction of doses. By the use of maximal therapeutic doses of the three drugs until an optimal response has been effected, my associates and I are finding that the length of time they are required is shortened. In spreading peritonitis this response usually is obtained in from five to seven days.

Dr. William Altemeier, Cincinnati: I wish to thank the two discussants for their pertinent comments. I am glad to see that the experiences of Dr. Lyons and Dr. Pulaski coincide so closely with ours, in that they find that combined therapy with the various chemotherapeutic agents is superior to that of any single agent, including penicillin. I would like to emphasize again that there is no specific treatment for secondary peritonitis and that successful management depends primarily on early surgical intervention and secondarily on adequate chemotherapy. Although there were no deaths in the cases of spreading peritonitis treated with streptomycin, it must be remembered that these were early cases which were more or less hand-picked, and that the absence of mortality is probably of no significance. With early diagnosis, prompt surgical treatment and combined chemotherapy, the mortality of spreading peritonitis should be reduced almost to nothing in the near future, except in those patients who are moribund or who have been neglected until the time of their admission.

# TREATMENT OF BRUCELLOSIS WITH STREPTOMYCIN AND A SULFONAMIDE DRUG

WESLEY W. SPINK, M.D.
WENDELL H. HALL, M.D.
JAMES SHAFFER, M.D.
and
ABRAHAM I. BRAUDE, M.D.
Minneapolis

Observations in brucellosis in human beings have indicated that the simultaneous administration of streptomycin and sulfadiazine is more effective therapeutically than when either drug is given alone.[1] Experimental studies with infected fertilized hens' eggs have also supported this conclusion.[2] Furthermore, it has been shown experimentally that the combination of streptomycin and sulfadiazine acts synergistically against the three species of Brucella.[3] In the initial communication from our clinic on the treatment of human beings with the combination, 9 patients were included in the study.[1c] The results were more satisfactory than had been obtained with any other form of therapy up to that time at the University of Minnesota Hospitals. A subsequent report embraced a total of 17 patients treated with streptomycin and a sulfonamide drug.[4]

Continued experience with this combined therapy in brucellosis in human beings has provided further evidence that it constitutes a satisfactory form of specific treatment. The purpose of this paper is to review the clinical results in a group of 23 patients, who were treated during the fourteen months prior to writing. It should be emphasized that the diagnosis of brucellosis was proved bacteriologically in 17 of the 23 patients. The causative agent in all of these cases was Brucella abortus. In the remaining 6 cases, there was sufficient epidemiologic, clinical and laboratory evidence to support a diagnosis of active brucellosis. This number of patients and the lapse of sufficient time after the completion of therapy should provide answers to certain pertinent questions that have arisen in this and other clinics. These included: What sulfonamide preparation should be used in combination with streptomycin? What are the optimum doses of streptomycin and a sulfonamide drug in cases of acute and chronic brucellosis, with and without complications? What are the undesirable reactions arising from the use of such a combination? How rapidly and consistently does the combination affect the clinical course of brucellosis? How frequently do clinical and bacteriologic relapses occur? Is the development of streptomycin-resistant strains of Brucella a clinical problem?

## OPTIMUM DOSES OF STREPTOMYCIN AND A SULFONAMIDE DRUG

In order to obtain information as quickly as possible relative to the value of streptomycin and a sulfonamide drug in the treatment of brucellosis in human beings, it was necessary not to vary the dosage schedules too greatly and to select one sulfonamide drug to administer with streptomycin. Investigations with several sulfonamide preparations in the therapy of experimentally infected chick embryos indicated that any one of several was effective, particularly when used with streptomycin. Early in the studies of human beings, sulfadiazine was selected for oral administration. Experimentally, it has been observed that streptomycin and sulfadiazine are effective against all three species of Brucella, namely Br. abortus, Brucella suis and Brucella melitensis. Sulfamerazine can be used instead of sulfadiazine, or the required sulfonamide drug may be administered in the form of equal parts of sulfamerazine and sulfadiazine. Sulfathiazole is not recommended for treatment because it is a more potentially dangerous drug than either sulfadiazine or sulfamerazine. Sulfadiazine has been administered in those doses which have maintained a blood concentration of 5 to 10 mg. per hundred cubic centimeters. An orally administered dose of 3 to 4 Gm. was used initially and then 1 Gm. every four hours. Frequently, one of the night doses was omitted routinely, in order not to disturb the patient. To insure alkaline urine, 12 to 16 Gm. of soda bicarbonate was given in divided doses in a twenty-four hour period. Precautions against renal complications included a careful check of the fluid balance, striving to have the patient void at least 1 liter of urine in twenty-four hours.

---

Read before the Section on Experimental Medicine and Therapeutics at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 23, 1948.

This investigation was supported (in part) by a research grant from the Division of Research Grants and Fellowships of the National Institute of Health, United States Public Health Service.

[4] Spink, W. W.: Pathogenesis of Human Brucellosis with Respect to Prevention and Treatment, Ann. Int. Med., **29**: 238, 1948.

Many in vitro tests with freshly isolated strains of the three species of Brucella showed that a concentration of 1.5 to 2.5 micrograms per cubic centimeter of streptomycin completely inhibited growth. It was apparent that many times these levels could be readily attained in the blood by the injection of moderate amounts of streptomycin. After the administration of 0.5 Gm. of streptomycin, blood levels of 15 to 20 micrograms were obtained. The first 2 patients in our clinic treated simultaneously with streptomycin and sulfadiazine were seriously ill and had been in ill health for several months. One had subacute bacterial endocarditis due to Br. abortus as a complication. Therefore, relatively large doses of streptomycin were employed. A total of 4 Gm. was given daily for fourteen days, and 6 Gm. of sulfadiazine was administered daily for twenty-two days. This patient recovered completely and has remained free of any evidence of brucellosis for fourteen months, but, as a result of the streptomycin therapy, a disturbing and slightly disabling dysfunction of the vestibular apparatus has persisted. The second patient was successfully treated with similar doses and has remained in good health for the same period of time. Because evidence was accumulating in the treatment of other infections with streptomycin that toxic reactions, especially involvement of the eighth nerve, were more likely to occur with the larger doses, it was decided to reduce the total dose of streptomycin administered. Accordingly, a total of 12 patients were treated with smaller doses of streptomycin. Five-tenths of a gram was injected every six hours for one week, and 6 Gm. of sulfadiazine was administered daily for total of three weeks. In a few instances, this total amount of streptomycin did not appear to be sufficient. Finally, the present recommended schedule was arrived at. Streptomycin is now administered in a dose of 0.5 Gm. every six hours for a total of 28 Gm. given in fourteen days. At the same time that therapy with streptomycin is started, an initial dose of 3 to 4 Gm. of sulfadiazine is given and then 1 Gm. every four hours for at least fourteen days and in some instances for twenty-one days. It has not been established clearly whether treatment with sulfonamide drugs should be continued for an additional week beyond the two weeks of combined treatment.

The only toxic reaction encountered with streptomycin in this series of 23 patients occurred in the first patient treated, as already mentioned. If the maximum daily dose of 2 Gm. is not exceeded, there is little danger of undesirable effect from streptomycin. Until evidence is offered in favor of larger doses, this maximum should be followed. Only 1 patient had evidence of a reaction to the sulfonamide drug. On the eighth day of treatment, the appearance of dermatitis and fever necessitated our discontinuing treatment.

### EFFECT OF COMBINED TREATMENT ON THE CLINICAL COURSE OF BRUCELLOSIS

As with other infectious diseases, the cases were divided into acute and chronic on the basis of the duration of illness. A case was considered to be of chronic disease if the illness had persisted for three or more months. Unfortunately, the literature on brucellosis is perpetuating a more special connotation for chronic brucellosis. The term has come to mean an obscure and indolent illness without localizing abnormal physical observations, with little or no elevation of temperature, with absence of demonstrable bacteremia and, frequently, absence of agglutinins and with dermal hypersensitivity to Brucella antigen often a deciding factor in establishing the diagnosis.

It is to be recalled that the acutely ill patient with brucellosis will often benefit considerably from bed rest. As in malaria and tuberculosis, reduction of physical activity to a minimum affects the clinical course of brucellosis favorably. This feature must be taken into consideration in the evaluation of specific therapy. Fortunately, for the present purposes, several of the patients had been in bed without sustained relief. There were 13 patients who had been ill for less than three months. Br. abortus was isolated from 11 of these patients. The effect of combined therapy on the clinical course followed a fairly definite pattern. Within a few days after beginning treatment, the patients experienced subjective improvement. However, in the febrile patient normal temperatures were not sustained until the seventh to tenth day of therapy. None of the 13 patients with acute brucellosis failed to show improvement following treatment. Combined treatment effected just as favorable results in the febrile chronic condition as in the acute condition. In a few instances, fever persisted until streptomycin therapy was discontinued on the fourteenth or fifteenth day. The immediate result in 2 patients with bone lesions was satisfactory, although each of these patients had been ill and incapacitated for nine months.

TABLE 1.—*Incidence of a Clinical Relapse or Persistent Bacteremia*

| Time Elapsed, Mo. | Number of Cases | Number of Cases with Relapse or Bacteremia |
|---|---|---|
| 12 to 14 | 3 | 0 |
| 8 to 10 | 6 | 2 |
| 6 to 8 | 3 | 1 (bacteremia) |
| 4 to 6 | 3 | 1 |
| 2 to 4 | 3 | 0 |
| Less than 2 | 5 | 1 (bacteremia) |
| Total | 23 | 5 |

It is of interest that although some patients remained well up to a year following treatment, a high titer of agglutinins persisted in the blood. In fact, in no instance did the agglutinins disappear from the blood following therapy. There is no relationship between the titer of the agglutinins and the well-being of the patient. Dermal hypersensitivity also persisted.

### BACTERIOLOGIC AND CLINICAL RELAPSES FOLLOWING COMBINED THERAPY

Brucellosis is a deceptive disease with respect to evaluation of any therapeutic agent or agents. Spontaneous remissions and relapses have been known to occur with such frequency that the term "undulant fever" is still rather descriptive of the illness. Another complicating feature has been revealed in epidemiologic studies being conducted in this clinic. There is evidence that recurrent attacks of the illness in some patients may not represent relapses, but rather reinfections.

In table 1 is presented the time that has elapsed since the completion of treatment in the 23 cases and, also, the number of patients who have had either a clinical relapse or persistent bacteremia. It should be stressed that in the evaluation of specific therapy in brucellosis one should make just as thorough attempts to isolate Brucella organisms from the patients after therapy as before. If this had not been done in the present series, the bacteremia of 2 of the patients after the completion of treatment would have escaped detection. Both of these patients appeared and felt well at the time the post-therapeutic bacteremia was present. No further treatment was given, and they have remained well symptomatically. One of these patients received streptomycin and sulfadiazine for nine days and one for two weeks. One had been ill for one week and the other for three months. The clinical course of 1 of these patients is shown in the chart. This patient had been sick for three months and had received streptomycin and sulfadiazine for nine days and then sulfadiazine for thirteen more days. Follow-up studies of this patient two months after leaving the hospital showed that he was well and abacteremic.

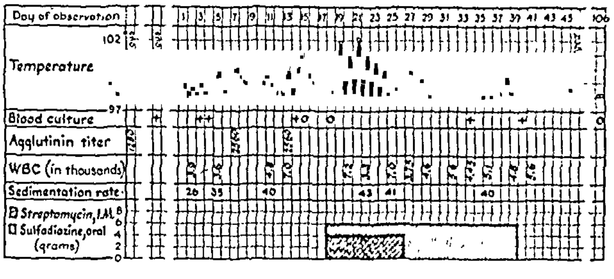

Chart showing the clinical course of a 60 year old man who was ill three months. (The sedimentation rate is expressed in millimeters per hour, Westergren.)

Only 3 of the 23 patients had a clinical relapse following treatment. However, 5 of the patients had been under observation for less than two months at the time of writing. One of the most remarkable instances of relapse was in a patient who had been ill for only three weeks. He received three courses of combined therapy, of nine, four and seven days each, and had a prompt clinical and bacteriologic relapse after each course. Finally, he was given streptomycin and sulfadiazine for fifteen days. At the time of last examination he had remained well and abacteremic for almost four months. A second patient had been ill for nine months and entered the hospital in a serious state of ill health with excruciating pain over the spine. He was given combined therapy for eight days, with dramatic improvement. He had a relapse four months later, with back pain due to spondylitis. He underwent another course of therapy, again with decided improvement. The third patient who had a clinical relapse was an instance of chronic brucellosis. In fact, he showed little improvement as a result of treatment. He had been in a state of ill health for over two years, suffering from weakness and an intolerance for physical activity. He had been thoroughly exposed to a herd of cattle with Bang's disease. Although he was afebrile and abacteremic, the subjective complaints and a significant titer of agglutinins for Brucella organisms warranted a trial of streptomycin and sulfadiazine for eight days. He recently completed a more prolonged course of treatment with the two drugs, followed by improvement, but the ultimate effect must await further observation.

In summary, then, experience with combined streptomycin and sulfadiazine therapy over a period of more than a year in 23 patients has revealed tht the clinical status of the acutely ill and febrile patient in the vast majority of cases is consistently improved as a result of treatment.

### APPEARANCE OF STREPTOMYCIN-RESISTANT STRAINS OF BRUCELLA AS A RESULT OF TREATMENT

As has already been stated, in vitro tests with over fifty strains of Brucella isolated from patients have shown that concentrations of 1.5 to 2.5 micrograms of streptomycin per cubic centimeter will completely inhibit growth of the organisms. In other words, strains of Brucella are sensitive initially to therapeutic concentrations of streptomycin. That sensitive strains of Brucella may become resistant to high concentrations of streptomycin both in vitro and in vivo has been demonstrated in this clinic. Hall and Spink[5] reported an instance in which a patient, who had subacute bacterial endocarditis due to Br. abortus, showed the appearance in his blood of Brucella organisms extremely resistant in vitro to streptomycin. This patient had received relatively large doses of streptomycin alone over a period of a month before the phenomenon was observed. Dr. James Shaffer, and more recently Dr. Ellard Yow, working in this laboratory, have demonstrated that a sensitive culture of Brucella contains a few highly resistant variants, in a proportion of a few resistant organisms to several billion sensitive organisms. The resistantce of Brucella to streptomycin is a genetic phenomenon, and a resistant culture results from the rapid multiplication of resistant variants originally present in the culture, and not as a result of adaptation or acquired resistance to the drug. A similar biologic phenomenon has been described for streptomycin and Hemophilus influenzae.

Table 2.—*In Vitro Resistance of Strains of Br. Abortus to Streptomycin in Patients with Persistence of Bacteremia After Treatment*

| Case Number | Dosage | In Vitro Resistance Before Treatment, Micrograms per Cc. | In Vitro Resistance After Treatment, Micrograms per Cc. |
|---|---|---|---|
| 1 | Streptomycin, 18 Gm. in 9 days; sulfadiazine, 13.2 Gm. in 22 days | 1.5 | 1.5 |
| 2 | Streptomycin, 29 Gm. in 15 days; sulfadiazine, 62 Gm. in 15 days | 1.5 | 1.5 |
| 3 | Course 1: streptomycin, 16.5 Gm. in 9 days; sulfadiazine, 66 Gm. in 9 days | 2.0 | 2.0 |
|  | Course 2: streptomycin, 8 Gm. in 4 days; sulfadiazine, 20 Gm. in 4 days | 2.5 | 2.5 |
|  | Course 3: streptomycin, 14 Gm. in 7 days; sulfadiazine, 62 Gm. in 13 days | 2.5 | 2.5 |
|  | Course 4: streptomycin, 43.5 Gm. in 15 days; sulfadiazine, 87 Gm. in 15 days | 2.5 | Not available |

In the light of the foregoing observations, it was of importance to determine whether the patients who had had bacteremia after the completion of treatment with streptomycin and sulfadiazine had cultures of Brucella containing predominantly resistant variants. Br. abortus was isolated from the blood of 3 patients after treatment. The data are summarized in table 2. It is to be noted that in no instance was the failure of therapy related to the appearance of a highly resistant culture

---

5. Hall, W. H., and Spink, W. W.: In Vitro Sensitivity of Brucella to Streptomycin: Development of Resistance During Streptomycin Treatment, Proc. Soc. Exper. Biol. & Med. 64: 403 (April) 1947.

of Br. abortus. Of particular interest is the patient who received four courses of treatment; after the third course of combined therapy no essential difference was manifested in the resistance of the recovered organisms to streptomycin.

It is not clear why streptomycin-resistant strains of Brucella did not appear after treatment. The most likely explanation is that the organism recovered from the blood after treatment may have come from foci not reached by the streptomycin in the body. In this manner, streptomycin would not have had the opportunity to kill the sensitive variants. An additional factor may be that streptomycin-resistant variants are less likely to multiply in the presence of another antibacterial agent such as sulfadiazine. This latter possibility is being investigated.

### COMMENT

Brucellosis still remains a relatively common type of infectious disease. Physical and mental debilitation are associated with a protracted illness. Now that a more satisfactory form of specific therapy is available, it becomes more urgent to diagnose and treat brucellosis in the early stages of the disease. The specific treatment of chronic brucellosis poses a special problem that cannot be satisfactorily answered at this time. Although therapy with streptomycin and sulfadiazine has been under evaluation in our clinic and in other clinics for over a year, an optimum schedule of doses of the two drugs must await further studies. Investigations are also progressing with other chemotherapeutic agents and antibiotics.

### SUMMARY

The simultaneous administration of streptomycin and a sulfonamide, especially sulfadiazine, has been utilized in the treatment of 23 patients with brucellosis over a period of fourteen months. It is recommended that 0.5 Gm. of streptomycin should be injected intramuscularly every six hours for a total of 28 Gm. given in fourteen days. At the same time that treatment with streptomycin is begun, an initial dose of 3 to 4 Gm. of sulfadiazine is given orally and then 1 Gm. every four hours for at least fourteen days. One of the doses of sulfadiazine may be omitted routinely during the night.

The foregoing type of combined therapy has been followed by a relatively low number of relapses; toxic reactions to either drug have not been serious, and the appearance of streptomycin-resistant Brucella has not occurred. While combined therapy has proved effective in the febrile and bacteremic patient, with and without complications, its effectiveness in the obscure and indolent forms of chronic brucellosis require further investigation.

Note.—Since this paper was presented, two major developments have occurred in the treatment of brucellosis. First, it appears that the antibiotic aureomycin is a more satisfactory therapeutic agent than the combination of streptomycin and sulfadiazine and is now recommended for therapy in proved cases (Spink, W. W.; Braude, A. I.; Castaneda, M. R., and Goytia, R. S.: Aureomycin Therapy in Human Brucellosis Due to Brucella Melitensis, J. A. M. A., 138:1145 [Dec. 18] 1948). Second, if the combination of streptomycin and sulfadiazine is to be used, dihydrostreptomycin should be substituted for streptomycin. Dihydrostreptomycin has just as good antibrucella activity as streptomycin and provokes a smaller incidence of vestibular dysfunction if the total daily dose is 2 Gm. or less.

## ABSTRACT OF DISCUSSION

Dr. C. Wesley Eisele, Chicago: I am gratified to have this additional confirmation of the value of a method of treatment which in the spring of 1947 was reported independently by Pulaski and Amspacher and by McCullough and myself. The number of reported patients treated by this method now totals 50. We have data on 24 additional patients treated by us or reported to us in personal communications, bringing the total to 74 cases. The diagnosis in all except 7 of these was culturally proved, and all three species of Brucella are represented. There is a second case of endocarditis due to Brucella treated by Dr. George Finch of Des Moines, with apparent recovery. The method now appears to be the most effective treatment known for acute brucellosis, and it also has some merit in the proved, long-standing chronic disease, but there are several factors which should definitely temper enthusiasm. First, there is the ever present difficulty of evaluation of any therapeutic agent in a disease, such as brucellosis, which runs an erratic and unpredictable course. Many patients with acute brucellosis recover promptly with bed rest alone. Failure or relapse occurred in 13 of our 74 cases. This approaches the 20 per cent level. Some of these may eventually be shown to be due to inadequate dosage. The actual relapse rate is likely to be considerably higher, because all except a few of the patients in these series have been followed for less than a year and many for as short a time as two or three months. The most critical and convincing evidence supporting the usefulness of this method is provided by 4 cases. These are the 2 cases with suspected endocarditis due to Brucella with apparent recovery (as far as I know, no patient with endocarditis ever recovered before), and the first 2 cases reported in which streptomycin and sulfadiazine separately failed but the subsequent simultaneous use of the two drugs was successful. Our experience with the toxicity of this combined drug therapy has not paralleled that reported by Dr. Spink. Even with the small doses of 2 Gm. a day for fourteen days, we have observed a discouragingly high incidence of toxic reactions. In addition to the usual vestibular damage, we have noted objective evidence of involvement of other cranial nerves, the third, fourth, fifth, sixth and seventh. We strongly recommend that this treatment be reserved for the seriously ill and seriously incapacitated patient, the one who is unlikely to recover without it, the one whose illness is serious enough to warrant the risks involved. The ideal treatment for brucellosis awaits discovery.

Dr. Max Michael, Atlanta, Ga.: My question concerns the possible mechanism of action of the combined chemotherapy as used. The sulfonamide drugs alone apparently are not effective in the treatment of acute proved brucellosis, nor is streptomycin; yet in the test tube they both seem to be effective against the agent. The reason sometimes given for the failure is that the organism had an intracellular position in the host, comparable to a virus infection. I wonder whether Dr. Spink can explain why combined therapy should seem to work.

Dr. Walter Bauer, Boston: I have one question sent up to the platform: In view of the fact that diagnosis of chronic brucellosis is made with great frequency and oftentimes on inadequate clinical and laboratory evidence, I wonder whether Dr. Spink would be willing to go so far as to state that this treatment, which is not without complications, should be withheld unless clinical and diagnostic evidence of the type he has presented is at hand?

Dr. Wesley W. Spink, Minneapolis: I am interested to hear that Dr. Eisele has seen such a high incidence of toxic reactions due to streptomycin and sulfadiazine. We have observed only 1 patient out of 23 who had a toxic reaction. I would like to ask Dr. Eisele how many patients he has personally treated, and, of those treated, how many had toxic reactions. As to why the combination of streptomycin and sulfadiazine is effective against Brucella, when neither drug alone is of much value clinically, I do not know. We have observed in the experimentally infected chicken embryo that the combination has given the best results not only in protecting the embryos but in sterilizing the tissues as well, and a large number of agents have been tested in this manner. The complete data will appear in *The Journal of Immunology*. We have shown that the action of the combination of streptomycin and sulfadiazine is synergistic and not merely additive.

As far as Dr. Bauer's question is concerned, I do not believe that this combined treatment should be withheld if bacteriologic proof of the disease is lacking. We have seen many cases of brucellosis in packing plant employees. These persons, from an epidemiologic, clinical and laboratory point of view, have brucellosis. Agglutinins for Brucella are present in a high titer. However, try as we might, we cannot isolate Brucella from blood cultures of over 25 per cent of this group. One reason for this cultural difficulty is that the colony count of Brucella in the blood is relatively low, as pointed out by the Mediterranean Fever Commission many years ago. However, I have never seen a bacteriologically proved case of brucellosis in a human being without agglutinins over a period of eleven years. Dr. Eisele and Dr. McCullough have had a similar experience. Therefore, in a suspected case of brucellosis with negative blood cultures and without agglutinins, or agglutinins present in a low titer, I would not utilize this combined treatment. The higher the titer of agglutinins, the more likely will there be positive blood cultures. In doubtful cases, we culture not only venous blood but also aspirated sternal bone marrow. We have also cultured Brucella from excised lymph nodes.

Dr. C. Wesley Eisele, Chicago: In reply to Dr. Spink's closing comment, our experience has been much less extensive, in part because of the selection of cases. We have treated 7 patients, 4 of whom have had toxic reactions.

# EARLY RENAL CARCINOMA IN SITU

## Detected by Means of Smears of Fixed Urinary Sediment

N. CHANDLER FOOT, M.D.
and
G. N. PAPANICOLAOU, M.D.
New York

More and more stress has recently been laid on the importance of early carcinomas which have not as yet broken out of their parent epithelium to invade surrounding tissue and are hence known as "carcinomas in situ." At present, carcinoma in situ is well recognized as a type in the breast, cervix and stomach. The term is beginning to be applied to Bowen's "precancerous dermatosis" of the skin and to exactly similar lesions in the esophagus and anus.

Carcinoma in situ is readily detected in biopsies of the breast and cervix uteri, provided that the surgeon has been fortunate enough to obtain specimens coinciding with the affected areas. In the skin it is usually easily diagnosed on gross inspection, and biopsy is simple and conclusive. While this is also in a measure true of such tumors in the anal canal, it is manifestly difficult or impossible to obtain biopsy specimens from the esophagus, stomach or urinary tract, where they are either invisible or inaccessible.

The recently improved technic of desquamative cytologic diagnosis should come to one's aid in these unfavorable instances, provided always that the cells of the tumor are desquamating and can be recognized in smears. Thus, gastric or esophageal washings, or urinary sediments, should afford a means of detecting carcinoma in situ before it has become visible through an optical instrument, like the gastroscope or cystoscope. In the renal pelvis visualization is impossible; one must depend on the roentgenograms of intravenous or retrograde pyelography, and in the carcinoma in situ these will give little information, as this incipient tumor is noninvasive and does not produce detectable scarring or distortion. Furthermore, it lacks the bulk that would cast shadows or alter the density of tissue.

The case described here is of a carcinoma in situ of the renal pelvis and collecting tubules that was invisible on gross inspection even after the kidney had been surgically removed. Nevertheless, smears from urine obtained by ureteral catheterization were repeatedly reported by one of us (G. N. P.) as "class 5," indicating the presence of cancerous elements. Microscopic examination of the organ revealed small areas in the calices and pyramids of this kidney in which there was unmistakable evidence of carcinomatous change in the caliceal epithelium and in that of many of the collecting tubules as well. The conclusion as to the value of examining smears of urinary sediments is therefore obviously favorable.

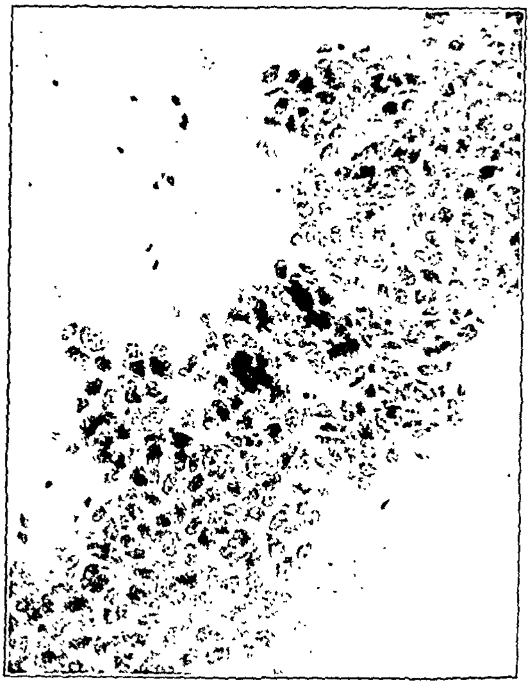

Fig. 1.—Enormous cluster of desquamated carcinomatous cells in smear of sedimented urine (X 265).

### REPORT OF A CASE

The patient was a white woman of 70 whose chief complaint was hematuria; aside from occasional burning in the urethral meatus she had had no symptoms referable to the genitourinary tract until approximately three weeks prior to admission to New York Hospital, when she noted a slightly bloody tinge to her urine. During the following fortnight there was hematuria every two or three days, and one week prior to admission she passed very bloody urine containing clots. Hematuria thereafter became continuous. She noted vague discomfort in both flanks, more pronounced on the left. Just before admission she suffered from frequency and urgency, passing a few cubic centimeters of bloody urine every twenty minutes or so. She had lost no weight.

*Family and Past History.*—Her family history is of some significance, as her mother and two sisters had died of cancer, the mother of "cancer of the liver." Her father's demise was attributed to "heart and kidney trouble." Two siblings were alive and well. Her history was otherwise irrelevant; she had been admitted to New York Hospital on three previous occasions for a variety of complaints, having suffered from a

*Dr. Carl J. Schmidlapp III, of the Department of Urology, New York Hospital, performed the nephrectomy, and the microscopic sections of the kidney for the study were supplied by Dr. John M. Pearce.*

prolapse of the urethral meatus, a urethral caruncle and arteriosclerosis.

*History in Hospital.*—Intravenous pyelograms showed a filling defect in the lower pole of the right kidney, but this was unconfirmed by subsequent retrograde pyelograms, which revealed nothing abnormal. During cystoscopy, however, it was noted that blood was issuing from the right ureteral orifice. Urinary samples were sent to the laboratory and smears prepared. The smear from a catheterized specimen from the left ureter was reported negative. Several specimens were taken from the right ureter; that of the ninth hospital day was classified as 3, and those of the fifteenth, seventeenth and twenty-second days were considered to represent class 5, or conclusive evidence of carcinoma. A sedimentation test and smear of urine from the bladder on the fifteenth day revealed class 4 cells. Thus there were three consecutive reports of class 5 cells in the smears from urine from the right ureter. One of these is illustrated in figure 1.

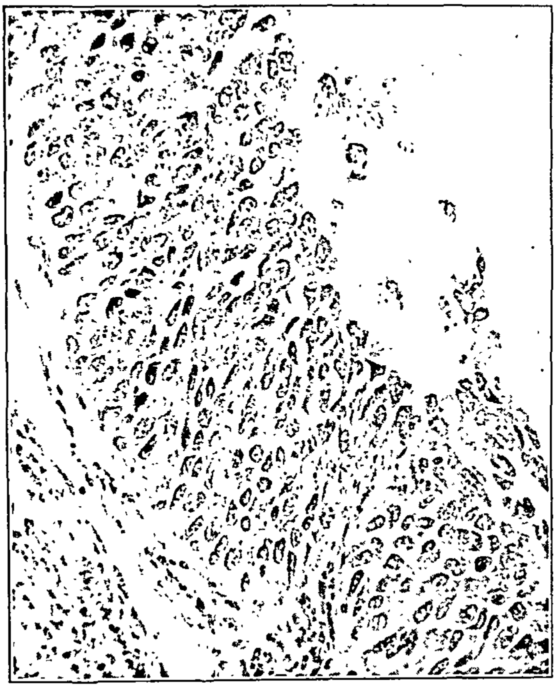

Fig. 2.—Transitional carcinoma confined to the mucosa of the calyx. The resemblance of this picture to that of any transitional carcinoma of the urinary tract may be noted (× 265).

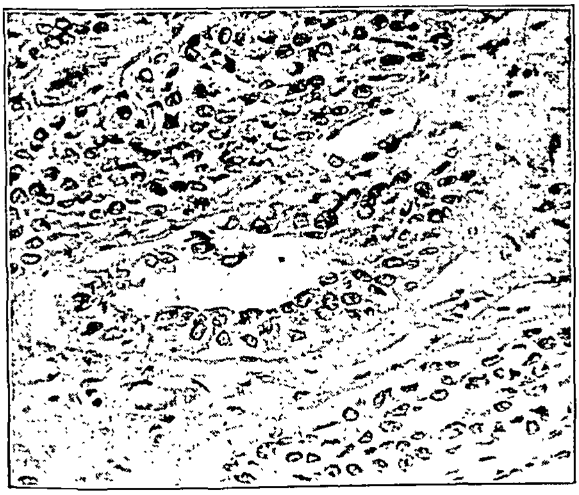

Fig. 3.—Carcinoma developing in the collecting tubules of the kidney. The cells differ considerably from those of the caliceal tumor; their cytoplasm is paler, and they tend to be less elongated (× 265).

On the basis of these reports and the observation of frank hematuria from the right ureter, the right kidney was removed on the twenty-fourth hospital day and sent to the Department of Surgical Pathology for examination.

*Pathologic Observations.*—The organ weighed 97 Gm. Nothing of importance was grossly discernible in its parenchyma, but in the inferior calyx there was a little blood and the mucosa showed areas of hemorrhage. There were scattered petechial hemorrhages in the mucosa of the ureter removed with the specimen. There was no gross evidence of carcinoma. The smears were reviewed, and the diagnosis of carcinoma was still maintained.

Microscopic sections were completed by the Department of Surgical Pathology from blocks taken from four calices, and carcinoma in situ was demonstrable in three of them. This was not limited to the pelvic mucosa, but existed both there and in many collecting tubules as well. There were two types of change: the pelvic epithelium showed early transitional carcinoma in situ (fig. 2), while that of the tubules was of the type generally known as "tubular carcinoma" (fig. 3). In the latter the caliceal epithelium adjoining and continuous with that at the debouchment of the collecting tubules was of the tubular, rather than the transitional, type. The cells were pale, more or less cuboidal and possessed large hyperchromatic nuclei that were manifestly abnormal. Anisocytosis and anisokaryosis were present, and many mitotic divisions were demonstrable. The histologic features of the growth thus coincided accurately with that of the smears of urinary sediment. Nowhere was there any evidence of invasion of the renal stroma; the tumor was completely in situ.

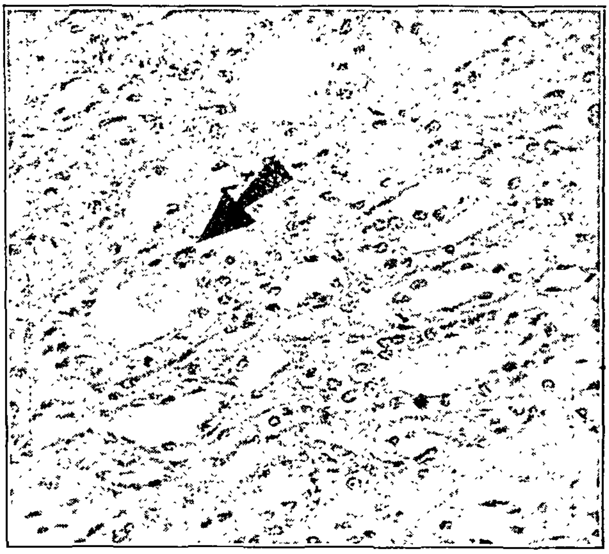

Fig. 4.—Section from above the tubular carcinoma; it shows relatively normal epithelium excepting for a few hyperchromatic nuclei and the very large metaplastic cell marked by the arrow (× 265).

## COMMENT

That the neoplasm involved the collecting tubules by direct extension along them from the pelvis (a mechanism that is all too frequently postulated for carcinomatous spread) was nowhere demonstrable. Instead, as the tumor was traced upward along these tubules it was seen to fade out gradually; a point was found where the epithelium became almost normal, but carcinomatous cells could be seen lying singly or in groups of two or three, intercalated among normal cells of the tubule (fig. 4). They were so integrated with these normal elements that they gave the impression that metaplasia was affecting single normal cells in a given area and that the abnormal products of this process were multiplying in situ and producing multicentric foci of carcinogenesis. Somewhat similar foci were readily found in the caliceal mucosa. It appeared likely that an entire district in the kidney, in and adjacent to the pelvis, was undergoing piecemeal metaplasia of its elements. There was nothing to indicate that a single focus in the caliceal epithelium had become carcinomatous and was expanding upward along the tubules. It is noteworthy that there were many clusters of cancerous cells either detached or in the process of desquamation from the surface of the tumor (fig. 5). *It is these clusters that appear in the smears* of urinary sediment, and the profuse desquamation of cancerous cells observed in this case is, therefore, strongly in support of the idea that carcinomas in situ do indeed shed their elements freely. This feature is pregnant with diagnostic possibilities in the case of carcinoma in situ in inaccessible areas of the body.

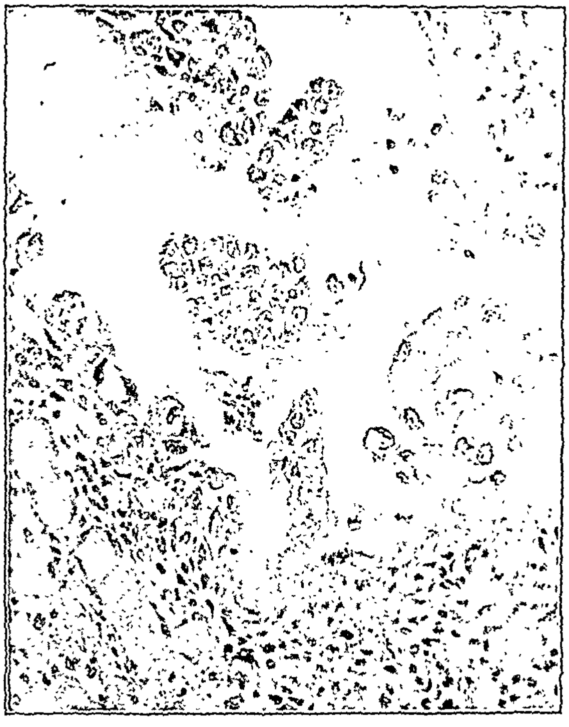

Fig. 5.—Clusters of desquamated cells in the tip of the calyx, ready for discharge in the urinary stream (× 265). (Compare with figure 1 and note similarity.)

There is little need for detailed discussion, as the facts speak for themselves. Whether a surgeon should undertake a nephrectomy on the basis of repeated positive reports of cancerous elements in the urine from the affected side might appear debatable; whether he should so proceed when these reports are supported by the presence of manifest ureteral bleeding on that side may seem less so. The main point to be borne in mind is the fact that in this case a tumor, invisible to the naked eye, was detected and ablated while it was still in its incipiency and the procedure was amply justified by the microscopic sections from the kidney in which it was developing.

Naturally, before undertaking this drastic course, the surgeon must have complete confidence in the acumen and competence of the cytologist who makes the diagnosis on the urinary smears. Unless the examiner be thoroughly versed in the technic and unless he make a diagnosis of "conclusive evidence of carcinoma, class 5," disastrous results might ensue. Another point might be stressed: for good results from nephrectomy in the case of these highly malignant tumors of the conducting apparatus, which have been found to be most refractory to surgical treatment (Foot and Humphreys[1]), it is imperative that they be recognized and removed before they have become invasive and metastatic. In the past this has proved to be almost impossible.

---

## MODIFICATION OF BIOLOGIC RESPONSE IN EXPERIMENTAL HYPERSENSITIVITY

GUSTAVE J. DAMMIN, M.D.
and
SAMUEL C. BUKANTZ, M.D.
St. Louis

Recently there has been wider acceptance of the view that a particular group of diseases and certain reactions to therapeutic agents occur on the basis of an acquired hypersensitivity. There is evidence that rheumatic fever, glomerulonephritis, serum sickness and periarteritis nodosa belong in this category,[1] and some have added to this group acute disseminated lupus erythematosus and scleroderma.[2]

The lesions of acute glomerulonephritis and rheumatic fever generally occur after a definite interval following infection, and lesions resembling periarteritis nodosa have appeared after an interval following the administration of certain drugs or a foreign serum.[3] It has generally been accepted that the development of host hypersensitiveness during this interval is the essential pathogenetic basis for the subsequent morphologic alterations characteristic of these diseases and that the lesions observed result from the union of the responsible antigen with its antibody in the tissues of the

[illegible]

sensitized host. The contention that an antigen-antibody mechanism is involved is further supported by the observation that an increased serum gamma globulin fraction is common to this group of diseases.[4]

The recognition of a hypersensitivity factor in this group of diseases has led to numerous experimental attempts to produce similar vascular and other lesions. Such lesions have been produced by Longcope,[1b] Gerlach,[1f] Vaubel,[5] Masugi,[6] Cavelti and Cavelti,[7] Knepper[8] and Klinge[9] and, since Rich and Gregory[10] reawakened interest in the problem, by a number of more recent investigators.[11] Most of these experiments have been performed with rabbits with large intravenously administered doses of horse serum as the sensitizing antigen. The considerable variation (0 to 88 per cent) in the incidence of the vascular lesions[11c, d] somewhat limits the usefulness of this experimental method as it has been used to the present. Much more study should be given to an analysis of the factors influencing the development of the unmodified lesion in the rabbit, particularly with a view to developing strains of uniformly high susceptibility.

Despite these limitations in the experimental approach, however, the lesions of serum hypersensitivity have been observed by some to occur with sufficient frequency to permit studies of the basic mechanism involved and methods of preventing the lesions, the ultimate objective being to discover agents useful in the treatment of the diseases in human beings. Most of the recent investigations have indeed been concerned with efforts to prevent the development of the experimental lesion.

Salicylates, numerous antihistaminics, anticoagulants and agents with specific toxic actions, such as colchicine and the nitrogen mustards, have been used in the experimental animal. Modification or prevention of the lesions by these agents has been attempted on the assumption that they might act by (1) inhibiting the antigen-antibody combination, (2) neutralizing the end products of antigen-antibody combination which might have deleterious effects on the tissues, (3) preventing an intracellular coagulative process which may lead to cell death[12] or (4) suppressing the production of antibodies. Many of these agents have been studied as well for an in vitro effect on antigen-antibody combination.

Kyser, McCarter and Stengle[11f] presented evidence that diphenhydramine hydrochloride (benadryl hydrochloride®) (Parke, Davis & Company) and drug *1627* (G. D. Searle & Co.), another antihistaminic agent, impeded the development of serum-induced myocardial lesions in rabbits. These observations have not been confirmed. Several investigators have found that the antihistaminic drugs do not interfere with antigen-antibody combination in vitro or prevent the formation of antibody by the sensitized animal.[13]

Salicylates have been used more frequently than other agents in attempts to prevent these experimental lesions. Their use stems from early observations by Swift and his co-workers, that salicylates impede antibody formation in immunized rabbits and human subjects while favorably affecting the course of human serum disease.[14] In attempts to define the basis for this effect, Coburn[15] demonstrated that antigen-antibody combination in vitro was decidedly impaired by salicylates. However, the concentration required was at least 30 times the therapeutic level achieved by maximal administration of the drug. Jager and Nickerson[16] have recently found a suppression of antibody formation and a pronounced reduction in local and systemic reactions to typhoid vaccine administered to human subjects maintained for three weeks on salicylates with plasma concentrations of 300 to 410 micrograms per cubic centimeter. To the contrary, however, Scherer[13e] found no depressing effect of salicylates on the production of Rh antibodies in the rabbit.

Contradictory results have been obtained by the several investigators who have studied the effect of salicylates on the development of vascular lesions in the serum hypersensitized rabbit. Smull, Wissler and Watson[11g] and Sullivan[11h] reported that salicylates inhibit the production of endocardial and diffuse arterial lesions, respectively. Ehrich and Forman,[11i] using doses of salicylates to the limit of tolerance, found, on the other hand, no effect on the development of the vascular lesions.

Ehrich and Forman[11i] also studied the effect of dicumarol.® They reported a slight inhibition of antibody production, no effect on the arterial lesions and a strong inhibition of in vitro antigen-antibody combination. They have also observed that colchicine exerts a decided inhibiting effect on antibody production and the development of arterial lesions.

Nitrogen mustards have been used in attempts to prevent the lesions of experimental hypersensitivity because of their known effect on inhibiting antibody production, as first demonstrated with the sulfur mustards by Hektoen and Corper.[17] Philips and his co-workers[18] used ricin in goats and found that an anamnestic antibody response could be inhibited by *tris* (β-chloroethyl)amine hydrochloride. Similar observations were made with the bis compound by Spurr,[19] who used typhoid bacilli as the antigen and the rabbit as the experimental animal, and by Janeway and his co-workers,[20] employing large doses of bovine gamma globulin in rabbits. The effect of this suppression of antibody formation on the lesions of experimental hypersensitivity is still under study by the latter group.

In our own approach to the problem we first studied the effect of intravenous administration of histamine to determine whether vascular lesions similar to those of experimental hypersensitivity could be so produced. In a series of 11 rabbits receiving daily intravenous injections of 0.1 mg. of histamine base per kilogram of body weight for periods varying from one to sixty-two days, with total administered dosage ranging from 0.55 to 13.6 mg., no such lesions were produced.

We have studied the persistence of circulating antigen, the development of circulating antibodies, the Arthus reaction and vascular lesions in rabbits receiving horse serum according to the method employed by Rich,[10a] and the influence on these phenomena of neohetramine® (N, N-dimethyl-N′-[p-methoxybenzyl]-N′ [2-pyrimidyl] ethylenediamine hydrochloride) (Nepera Chemical Company), diphenhydramine hydrochloride, heparin and methyl-bis (β-chloroethyl) amine hydrochloride. The serologic studies were performed on serums obtained at weekly intervals. The tests for antigen employed a rabbit anti-horse serum in a tube centrifugation technic. A similar method using horse serum in a dilution of 1 : 10,000 was employed in testing for antibody. Direct observations of the Arthus reaction were made immediately and twenty-four hours after the injection of horse serum into the dorsal skin. In addition, fluorescein was used to study the reaction in the following manner: Immediately after intradermal injection of serum, fluorescein was injected intravenously and the sites observed under ultraviolet rays.[21] When fluorescence occurred it appeared immediately at the site, increased only slightly in intensity for about twenty minutes and subsided within several hours. It was noted that the normal rabbit skin seldom reacted to histamine with either erythema or whealing and that histamine sites generally did not fluoresce when studied with this technic. In view of these and subsequent observations, it seems likely that the substances liberated in the Arthus reaction in rabbits do not bear a close relationship to histamine.

In the first experiment with antihistaminic drugs, 14 rabbits received horse serum and 6 of these were given neohetramine® subcutaneously in doses of 10 mg. per kilogram of body weight twice daily. In all 6 rabbits receiving neohetramine,® antibodies, Arthus reactions and arteritis developed. In the 7 serum control animals tested, antibodies and Arthus reactions developed and 5 of this group had arteritis. In the doses used, neohetramine® did not affect the development of circulating antibodies, the Arthus reactions or arterial and endocardial lesions.

In the second experiment, 10 rabbits received horse serum and 6 were given benadryl® subcutaneously, in doses of 10 mg. per kilogram of body weight twice daily. Antibodies developed in all of the rabbits, and all but 1 receiving benadryl® showed Arthus reactions. One of the rabbits receiving diphenhydramine hydrochloride showed arterial lesions, whereas none were found in the untreated group. It is of interest that 2 of the rabbits in the group treated with diphenhydramine hydrochloride and 4 in the untreated group died in shock on the twentieth or twenty-first day following the second injection of horse serum intravenously. In none of these 6 rabbits were vascular lesions seen.

In summary of the first two experiments it may be stated that (1) in all animals, whether or not they had been treated with antihistaminic drugs, antibodies developed, (2) all of the rabbits except 1 in the group treated with diphenhydramine hydrochloride showed Arthus reactions of varying intensity and (3) the incidence of arterial lesions bore no relationship to the occurrence of anaphylactic shock or to treatment with the antihistaminics. There was considerable difference in the incidence of vascular lesions in the two experiments: 85 per cent in the first and only 10 per cent in the second experiment.

In a third experiment, bovine gamma globulin (The Armour Laboratories), and diphenhydramine hydrochloride were used. Gamma globulin was injected intravenously in single doses of 1.0 Gm. per kilogram of body weight into 10 rabbits. Five of these animals also received diphenhydramine hydrochloride subcutaneously in doses of 10 mg. per kilogram of body weight twice daily for sixteen to eighteen days, at which time all rabbits were killed. In all of these animals circulating antibodies and well defined Arthus reactions developed. No arterial or endocardial lesions were observed in any of the animals.

All rabbits in these three experiments either maintained their weight or increased in weight throughout the period of observation.

Experiments with 21 additional rabbits that were given intravenous injections of horse serum were complicated by the occurrence of an epizootic diarrhea. Eight of these rabbits received daily doses of diphenhydramine hydrochloride; 5 received neohetramine,® and 8 were controls receiving serum only. Five of the 21 animals were killed on the twenty-eighth to the thirty-first day following administration of the serum; 6 died between the fourteenth and twenty-third days and 10 between the first and eleventh days. Circulating antibody and cutaneous hypersensitivity were present in those surviving at least fourteen days, but neither arterial nor endocardial lesions were found. Because of the complicating disease, these 21 rabbits have not been included in our calculations of the incidence of vascular lesions. It is still of interest, however, that in control and treated animals in this group Arthus reactions and circulating antibody developed, again independently of vascular lesions.

Six sensitized rabbits were selected for an experiment to determine the effect of heparin on the Arthus reaction. Cutaneous sites were injected with 0.1 cc. amounts of horse serum. Three hours later 50 mg. of heparin in Pitkin's menstruum were injected subcutaneously. About ten hours later, when the clotting time was decidedly prolonged, a second series of intradermal injections of horse serum was made. The immediate and delayed reactions before and after administration of heparin were of equal intensity. Sections of the sites injected before and after administration of heparin showed pronounced edema and vascular necrosis. the tissue reaction after heparin being somewhat more intense.

The unpredictable and generally low incidence of vascular lesions in horse serum-sensitized rabbits led us to a brief investigation of local passive transfer as a tool to study further the nature of in vivo antigen-antibody reactions and the agents which might modify this reaction. This study is still in progress and has been only moderately successful to the present, apparently because of the comparatively low antibody content of the serums used.

Our most recent studies have been concerned with the effect of nitrogen mustard on the antibody production, Arthus reaction and vascular lesions in horse serum-sensitized rabbits.[22] Five rabbits were initially given intravenous injections of 0.5 mg. per kilogram of body weight of the bis compound each fourth day for a total of seven injections. On the second day after the third injection each rabbit received intravenously 10 cc. of horse serum per kilogram of body weight. The same amount of horse serum was given to each of 5 rabbits comprising a control group. In all rabbits receiving nitrogen mustard a bleeding tendency and pronounced luekopenia developed. On the seventeenth day all 10 animals were killed. None of the rabbits treated with nitrogen mustard showed endocardial or arterial lesions. Four of the 5 controls showed arterial and/or endocardial lesions. All 5 of the untreated rabbits showed circulating antibody on the seventh day after serum injection. whereas none of the rabbits treated with nitrogen mustard had circulating antibody at this time. Serum pools prepared from each group on the day the animals were killed were studied by means of the quantitative precipitin reaction for total antibody content. The untreated group had approximately twice as much circulating antibody as the group treated with nitrogen mustard.

The intensity of the Arthus reactions manifested by the two groups was compared. Parallel cutaneous sites were prepared by intradermal injection of 0.2 cc. amounts of horse serum diluted 1 : 1, 1 : 5, 1 : 10, 1 : 20 and 1 : 40. Immediate reactions were of approximately equal intensity for the two groups as observed by the fluorescence technic, but a striking difference in the intensity of the reactions was noted at twenty-four hours. All in the untreated group showed hemorrhagic Arthus reactions in the two highest concentrations of horse serum, whereas none of the rabbits treated with nitrogen mustard showed hemorrhage at any of the sites. The untreated group showed moderately intense reactions to the higher dilutions of horse serum, and only 1 in 5 did not react to the 1 : 40 dilution, whereas the reactions of the treated group diminished rapidly in intensity with increasing dilution, only one of the 5 showing any reaction in the 1 : 40 dilution.

## COMMENT

The clinical evidence reported supports the view that certain diseases and reactions to some drugs and foreign proteins occur on the basis of an acquired hypersensitivity. The exact nature of the antigens and antibodies involved in most instances has not been determined. Morphologic changes resembling those of the human diseases, however, have been produced in the experimental animal by injections of foreign proteins. This resemblance appears close enough to encourage the search for agents capable of modifying the experimental lesions as a guide to the development of measures useful in the prevention or treatment of the diseases in human beings.

The unpredictable occurrence of the lesions has, to date, impeded advances by this experimental approach. Genetic, constitutional and other factors comparable to those operative in determining in which persons acute glomerulonephritis or rheumatic fever will develop may also determine the incidence of vascular and other lesions in sensitized rabbits. An analysis of these factors and the development of constantly reacting strains of experimental animals are needed. Until these factors are better controlled and appropriately reacting strains are developed, the use of passive transfer may offer a partial solution.

Since the basic mechanism of tissue alterations in hypersensitivity is presumed to be an antigen-antibody combination in tissue, there has been much interest in determining the relationship of antibody levels to general and local anaphylaxis and vascular lesions. Studies by Grove[23] and Jackson[24] demonstrated a lack of correlation between antibody level and the occurrence of general anaphylaxis, but a direct correlation between antibody levels and the severity of the Arthus reaction has been observed repeatedly.[25] In regard to the relationship between vascular lesions and Arthus reactions, Fox and Jones[11a] reported a direct correlation, systemic vascular lesions occurring with the severer necrotizing Arthus reactions. Hopps and Wissler[11b] reported "poor quantitative correlation" between "the degree and extent of arteritis" and precipitin formation or cutaneous hypersensitivity. In our own experiments we were unable, on the basis of antibody response, the occurrence of anaphylactic shock and the intensity of the Arthus reaction, to predict which rabbits would exhibit arterial lesions. The only correlation in this respect was the invariable presence of circulating antibody and Arthus reactions in those rabbits with systemic vascular lesions. Some host factor in addition to, or separate from, the humoral antibody response may well be operative in the pathogenesis of the vascular lesions of experimental hypersensitivity. In this regard, the experiment with nitrogen mustard is of particular interest. Our observations showed nitrogen mustard to suppress development of antibody, cutaneous hypersensitivity and vascular lesions. Whether the parallel suppression of these phenomena indicates their interdependence is under investigation.

That the occurrence of vascular lesions may be related to an ability to produce antibody is suggested by a study of Callender and Race,[26] who reported a patient with diffuse lupus erythematosus showing a "remarkable liability to undergo isoimmunization" and "proneness to make isoagglutinins in response to the introduction of antigens which are ignored by most people."

In summarizing our work and reported attempts to prevent or modify the lesions in horse serum–sensitized rabbits it becomes apparent that (1) the antihistaminics, diphenhydramine hydrochloride and neoheteramine,® have no demonstrable effect on antibody production, in vitro antigen-antibody combination or the development of Arthus reactions and vascular lesions, (2) the effect of salicylates on these phenomena has been neither constant nor profound but deserves further study, (3) the anticoagulants have demonstrated no inhibiting effect on the lesions, but dicumarol® has been shown to inhibit in vitro antigen-antibody combination, and (4) among agents with particular cytotoxic properties, the nitrogen mustards effected pronounced inhibition of antibody production, Arthus reactions and vascular lesions. Therefore, of the agents investigated thus far for their ability to modify the development of vascular lesions in the horse serum–sensitized rabbit, that which exerted a profound depressing effect on the development of antibodies and the Arthus reaction was found also to be most effective in preventing the vascular lesions, namely, the nitrogen mustard, methyl-*bis* (β-chloroethyl) amine hydrochloride.

## ABSTRACT OF DISCUSSION

Dr. Samuel M. Feinberg, Chicago: The production of arterial lesions following the injection of horse serum or the use of sulfonamide drugs created a great stir among those concerned with allergic phenomena. Drs. Dammin and Bukantz have shown that the production of such lesions is by no means constant or predictable, an observation which immediately throws doubt on any type of experiment attempting to modify the genesis of such vascular changes in a small series of animals. They have shown further, contrary to some previous reports, that the use of antihistamine drugs does not prevent the formation of the lesions. This, coupled with their inability to produce vascular lesions by injections of histamine, leads them to believe that histamine is not the basis for this action. Such an inference is not necessarily true. That antihistamine drugs given repeatedly after serum administration in human beings does not prevent the onset of serum sickness is well known. Yet, these same drugs relieve the symptoms of the latter, probably by their antihistamine action. By the same token, it would be possible to conceive that periarteritis nodosa may be caused by histamine and yet not be prevented by antihistamine drugs. Since the lesions are irreversible, no symptomatic benefit might be expected. The negative results in the experiment in which histamine was injected intravenously in no way precludes the possibility of localized and concentrated release of histamine being responsible for the lesions of arteritis. The lack of inhibition of antibody formation confirms my experience. This is significant when one considers what effect these drugs might have on the production of protective antibodies which one attempts to produce by specific desensitization in order to give the patient clinical immunity. The question frequently arises: Do the antihistamine drugs interfere with the effects of desensitization? The answer, from my experience, strengthened by the work of these authors, is that they do not. The experimental work with nitrogen mustards is stimulating. I hope that the doctors will not rush to treat patients with rheumatic fever and similar diseases with these compounds. The toxic reactions to the nitrogen mustards are by no means slight. In addition, there is a great probability that any agent which will prevent or destroy a sensitizing antibody will also similarly affect desirable antibodies, such as those having to do with the protection against infectious disease.

# COARCTATION OF THE AORTA

HERBERT D. ADAMS, M.D.
DAVID J. RUTLEDGE, M.D.
and
CARLTON R. SOUDERS, M.D.
Boston

The examination of a large proportion of the youths of this country by the various examiners of the selective service boards resulted in a considerable number of rejections for military service because of persistent elevation of the blood pressure. Many of these persons were advised to consult their family physicians for advice and treatment. A small but important percentage of them are suffering from coarctation of the aorta. The prognosis in the past for patients with coarctation of the aorta has been poor because of the propensity of the condition to result in heart failure, rupture of the aorta above the coarctation, cerebrovascular accident or subacute bacterial endocarditis. The recent development of a surgical technic for correcting this anomaly, which when untreated results in such a limited life expectancy, makes it imperative that all physicians be alert to the possibility of this condition when confronted with hypertension in a young person.

There is little to add to the excellent reviews covering the general aspects of coarctation of the aorta. However, we would like to review some of the diagnostic points. Generally speaking, the diagnosis is not difficult if the examiner considers the possibility of the presence of coarctation. Most patients with coarctation of the aorta have no symptoms but present themselves because a routine physical examination has disclosed a persistent elevation of the blood pressure. Not infrequently a diagnosis of essential hypertension is made and they are referred for lumbodorsal sympathectomy. Symptoms such as headache, dizziness, nervousness and tension, while they may occur, usually are absent. If the condition has persisted until the myocardial reserve is diminished, dyspnea may be present on exertion. Unfortunately, in some cases the first symptoms may be related to an accident to the vascular system. When examining a hypertensive patient, the physician should always check the abdominal aorta and femoral arteries for pulsations. If they are diminished or absent, coarctation of the aorta should be suspected and confirmatory evidence sought. The presence of pulsations in the dorsalis pedis and posterior tibial arteries is not sufficient to exclude coarctation of the aorta, since pulsations may occasionally be present in that condition when collateral circulation is adequate. If pulsation in the

26. Callender, S. T., and Race, R. R.: A Serological and Genetical Study of Multiple Antibodies Formed in Response to Blood Transfusion by a Patient with Lupus Erythematosus Diffusus, Ann. Eugenics 13: 102, 1946.

From the Department of Surgery (Dr. Adams) and the Department of Internal Medicine (Dr. Rutledge and Dr. Souders), The Lahey Clinic.

aorta and femoral arteries is absent, a careful search should be made for evidence of unusual pulsations in the intercostal arteries. These arteries play an important role in the development of the collateral circulation, and their enlargement may be so great as to be easily detected by palpation. Campbell and Suzman [1] have called attention to a new diagnostic sign in cases of coarctation of the aorta. They noted that when the patient stoops or bends forward, with the arms hanging by the side, collateral arteries may be seen under the skin of the back and sides of the thorax where none were visible before. They explain the phenomenon by the fact that this position widens the costoclavicular space, which in the erect posture is narrow enough to cause slight obstruction to the dilated subclavian artery in coarctation of the aorta. Widening of the space removes the obstruction and allows the vessels to fill.

The arterial pressure in the arms should be compared with that in the legs. Normally, it is higher in the legs than in the arms, but this situation is reversed when coarctation is present. Indeed, the pressure in the legs may be so low that it cannot be measured, which is also a highly significant observation.

Auscultation of the chest may reveal a characteristic murmur of coarctation of the aorta. It is loud, rough, systolic in time, clearly heard along the left sternal border and usually equally clearly heard in the back along the left margin of the vertebral column. Not infrequently, the systolic murmur will be followed by a soft blowing diastolic murmur. A systolic thrill may or may not be present. This murmur has often led to the erroneous diagnosis of rheumatic heart disease. The loud quality of the murmur in the back, however, tends to differentiate the two conditions.

Theoretically, examination of the ocular fundi should prove helpful in the differential diagnosis, as one would not expect to find evidence of unusual sclerosis or spasm of the retinal vessels in coarctation. Several patients with coarctation have recently been seen who presented some unusual features. Although the vessels of the fundi did not show the postangiospastic state, evidence of unusual sclerosis or the usual tortuosity seen in arteriosclerosis, they did present a wavy appearance with broad sweeping curves, while the vessel walls presented a normal appearance.

The roentgenogram of the thorax often renders valuable aid to the diagnosis of coarctation of the aorta. All too frequently, the diagnosis is first suspected by the roentgenologist. The increased blood flow through the intercostal vessels results in the characteristic notchings along the inferior margins of the ribs. This observation may be absent, however, and one should not rely on it to make the diagnosis. Reifenstein, Levine and Gross [2] reported its presence in 75 per cent of their series of 43 cases.

Angiography with 70 per cent iodopyracet injection (diodrast®) (fig. 1) by the method of Robb and Steinberg [3] may sometimes be used. While seldom required for the diagnosis of coarctation, it may give information which is helpful to the surgeon in planning the type of operation and surgical approach. In this technic, after proper preparation, 40 cc. of the iodopyracet is injected through a cannula into an antecubital vein as rapidly as possible, and several roentgenograms of the thoracic area are made in rapid succession as the concentrated opaque material progresses through the various chambers of the heart and great vessels. The time of exposure after injection has been determined previously by measuring the circulation time from arm to lung and arm to tongue by the use of ether and dehydrocholic acid (decholin®) or calcium gluconate. As many roentgenograms are made as is possible with the equipment available. Since the time for the progression of the iodopyracet injection through the heart and vessels is a matter of a few seconds, some arrangement must be made for rapid change of cassette.

The value of the method is limited by the difficulty of exposing several films at proper intervals and the fact that the opaque medium, after passing through the pulmonary artery, the lungs and back to the heart, may be so diffused as to cast only a faint shadow in the region of the aorta where it is most desired.

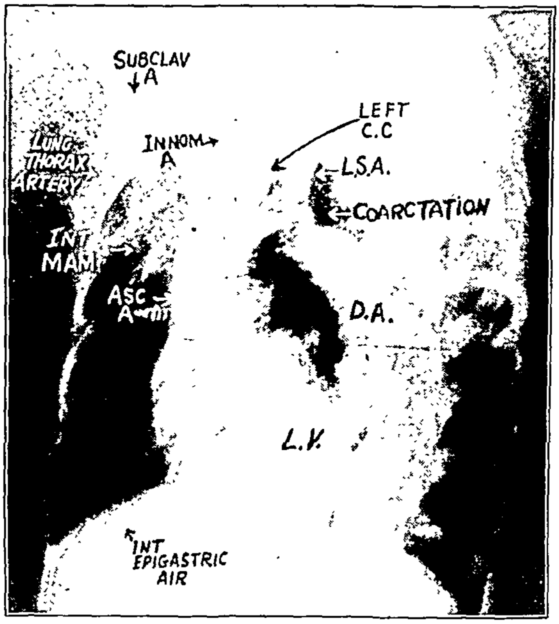

Fig. 1.—Angiograph with excellent visualization of coarctation. (Angiography supplied by Dr. Israel Steinberg, New York; published with permission of Year Book Publishers, Inc., from "Vascular Diseases in Clinical Practice," by Dr. Irving S. Wright, 1948, p. 65.)

Most patients have a considerable reaction of a vasomotor type to such rapid injection of iodopyracet, and a temporary period of syncope or shock ensues. Urticaria has occurred and may prove troublesome, and death has been reported following the test.

The procedure should not be undertaken without adequate equipment, a trained team and a careful consideration of the value to be gained weighed against the possible dangers. Nevertheless, at times this method may serve to show the position, degree and extent of the narrowed area of the aorta and the amount of collateral circulation, and for these reasons may be worth while.

The age of the patient has an important bearing on the selection for surgical treatment. The vessels of younger patients lend themselves to this type of operation better than those of the older patients, since they are more elastic and less friable. This is especially important if the constricted area is to be resected and the two ends of the aorta are to be anastomosed. Gross[2] placed the age limit between 6 and 25 years for this type of operation. Since the diagnosis may not be made until the patient is in his middle or late twenties, the surgeon should be prepared to carry out procedures other than the direct anastomosing of the two portions of the aorta. It is in these cases that the operation of Blalock and Park[4] warrants consideration. In this procedure the left subclavian artery is anastomosed to the descending aorta below the site of the coarctation. This method was used successfully in a man 34 years of age, according to reports from the Mayo Clinic.[5]

### MANAGEMENT IN FIVE CASES

In the past year we have resected five coarctations in adults, all of whom have survived their operations without complications and have subsequently had a lowering of their blood pressure to within normal levels. Their ages and sex, respectively, were: male 24, male 21, female 36, male 20 and male 35. Their preoperative systolic blood pressures averaged well over 200 mm. and their diastolic over 100 mm. Interestingly enough, these patients required one to three weeks after operation for stabilizing of their blood pressure at from 140 to 150 mm. systolic and from 80 to 90 mm. diastolic. They all remained in the hospital three weeks following operation, were kept recumbent with medium head rest for the first week, were allowed to sit over the edge of the bed for increasing intervals during the second week and were allowed up and mobilized gradually during the third week before discharge. Their postoperative courses were uniformly smooth, comfortable and uncomplicated. They all had intercostal drainage on suction for five to seven days after operation, and none required thoracentesis for a later effusion. Administration of penicillin was continued during the first week postoperatively and for at least forty-eight hours after the tube was removed. An oxygen tent was used on the patient's return from the operating room, but continued only until the following morning, when it was ascertained definitely that the left lung was well expanded and functioning adequately, and then the patient was gradually removed from the oxygen tent during the first and second postoperative days.

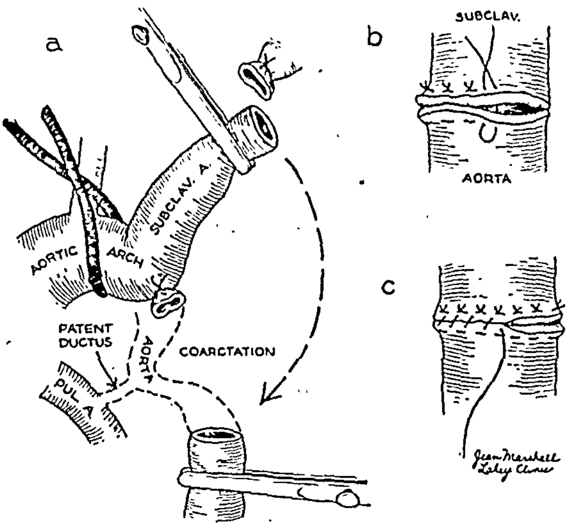

Fig. 2.—*a*, Resection of coarctation and mobilization of subclavian artery for end to end anastomosis with descending thoracic aorta; *b*, detail of end to end anastomosis, everting interrupted sutures around the entire circumference; *c*, everted edges reinforced with continuous sutures, each covering half the circumference.

All 5 patients were operated on under endotracheal ether anesthesia administered by highly trained anesthetists, on whom rests considerable responsibility for the maintenance of the general status of these patients throughout a long and hazardous procedure. The left thorax was opened widely through a posterolateral incision, resecting the fifth rib and cutting the fourth, sixth and seventh ribs behind their angles. In going through the thoracic wall, extensive arterial collateral circulation was encountered throughout the scapular and thoracic wall muscles. The intercostal vessels were greatly enlarged, and the fifth and sixth were ligated and sectioned posteriorly to facilitate exposure. An excellent exposure was thus obtained, in spite of the fact that several of these patients were extremely heavily muscled and of stocky build. The mediastinal pleura was then opened and the coarctation exposed.

Two general types of coarctation were encountered. In the first 3 patients the coarctation consisted of a decidedly narrowed and greatly distorted section of aorta about 1½ inches (3.75 cm.) long, beginning immediately distal to the point of origin of the left subclavian artery. This coarctated section curved sharply inward toward what appeared to be a short thick ligamentum arteriosum, but which in several patients proved to be a patent ductus arteriosus of very small caliber. The strictured area made roughly an "S" type of curve and gave the impression that this distortion was due to a contracture of the ductus arteriosus. Proximal to the coarctation the aorta was dilated at the base of the subclavian artery. This bulbous section was extremely short and the coarctated section was proportionately long, so that it was not possible to resect the coarctation and do an end to end anastomosis of the aorta without considerable tension. The left subclavian artery, however, was approximately three times its normal diameter and about equal in diameter to the aorta beyond the coarctation, that is, the descending part of the aorta. Four sets of intercostal arteries were ligated at their origin from the aorta in this region. These were of tremendous caliber, very short and friable and had to be handled with extreme care. The ligamentum arteriosum or the ductus arteriosus, if patent, was then sectioned, the coarctation mobilized and resected and the aorta closed at the base of the subclavian artery. The distal aorta was controlled by a Bradshaw[6] clamp and the transected end left open for anastomosis with the subclavian artery. The subclavian artery was then mobilized, its branches tied and divided and, after placement of a catheter around the arch of the aorta proximal to the subclavian artery for added safety, a Bradshaw clamp was applied to the subclavian artery and the artery transected as far distally as possible (fig. 2). The end of the subclavian artery was then readily swung downward for an end to end anastomosis with the descending thoracic aorta, thereby forming a perfect arch. In all adult patients the walls of both vessels are friable and thin, and it was thought that it would be poor judgment to use the usual methods of depending only on continuous everting sutures. Therefore, the anastomosis was carried out with meticulously placed interrupted everting mattress sutures around the entire circumference of the anastomosis. These sutures were of number 000 deknatel* silk and included all layers of the vessel wall; the edges were carefully everted with apposition of intima to intima. This everted suture line was then reinforced by two continuous over and over sutures of similar material, each suture covering half the circumference of the anastomosis. This made a firm nonleaking suture line after the clamp distal to the anastomosis had been removed and the clamp proximal to the anastomosis gradually released. There was a slight fall of blood pressure at this point, but no appreciable change in pulse. The mediastinal pleura and the thorax were closed, leaving the intercostal catheter for suction.

---

In the last 2 cases a second type of coarctation was encountered in which the area of coarctation was relatively short. There was decided narrowing and contracture at the level of the ligamentum arteriosus over an area of approximately 2 cm. In addition, the section of aorta between the coarctation and the subclavian was of sufficient length (1.25 cm.) to make a primary end to end anastomosis of the aorta. Three sets of intercostal vessels were ligated and the coarctation mobilized. The aortic arch distal to the left subclavian origin and a portion of the subclavian were also mobilized. Clamps were then placed across the arch of the aorta between the subclavian and the left carotid and a second clamp applied to the subclavian. A third clamp was placed on the aorta distal to the coarctation. The coarctation was resected and a careful end to end anastomosis of the aorta carried out, with the same technic as described previously, with interrupted everting mattress sutures around the entire periphery of the anastomosis, reinforced with several continuous sutures.

### COMMENT

It is interesting to observe that in none of these 5 patients was severe shock or circulatory collapse noted when the aortic clamps were removed after the anastomosis was completed. This has been reported repeatedly and deserves some comment, and a possible explanation of the cause, and some suggestions as to the management of this complication. In the subclavian aortic anastomosis of this type, a large proportion of the aortal flow is diverted which formerly passed through the subclavian system into the new aortic channel; therefore, blood pressure drop or circulatory collapse has not been observed in these cases. In the direct aortic or primary anastomosis, however, there is no diversion of this large subclavian flow, and when, in addition, a large aortic flow is opened up by removing the clamps it is obvious that this would cause a decided drop in blood pressure. It is therefore suggested that, as carried out in these cases, in the primary anastomosis of the aorta the subclavian be kept shut off while the aortic clamps are removed, and then, after the patient has adjusted to this minor drop in blood pressure, the clamp should be removed slowly from the subclavian artery. In this way it is possible to avoid having both these large channels open at the same time, with resultant decided lowering of the blood pressure. It is also interesting to note that there was a third minor drop when the lung was reexpanded and the pulmonary vascular bed increased as well. It is likewise advisable to have two infusions running at all times in this type of case, because of the hazard of sudden severe hemorrhage at any point during the procedure and, also, so that it is possible to run in large quantities of blood at the time the clamps are removed, if this proves necessary.

### SUMMARY

With surgical treatment now available, physicians should be particularly alert for cases of coarctation of the aorta, especially when evaluating hypertension in the young adult. Since this surgical procedure is safer and the results more satisfactory when performed during childhood, it is urged that all physicians and pediatricians make a comparison of the blood pressure in the upper and lower extremities as part of a routine general examination of children under their care.

In adults, the diagnosis should be made before the advanced deteriorating effects of the hypertension have produced irreversible systemic changes. If this is done, these adult patients can be safely operated on and good results obtained. The operations of choice are excision of the coarctation and end to end anastomosis of the ends of the aorta, or, if the strictured area is very long, the left subclavian artery can be utilized as described.

One of the major serious postoperative complications —hemorrhage from the suture line—can be avoided by using interrupted everting sutures around the entire circumference of the anastomosis, reinforced by continuous sutures over this everted edge. This is particularly important when dealing with the thin friable wall encountered in adult patients. Suggestions are also made to prevent pronounced circulatory collapse at the time of removal of the aortic clamps and opening up this large new vascular bed.

# IONIZING RADIATION INJURY

## Its Diagnosis by Physical Examination and Clinical Laboratory Procedures

LIEUTENANT COMMANDER EUGENE P. CRONKITE, M.C., U.S.N.
Bethesda, Md.

Prior to the advent of the cyclotron in 1931, sources of exposure to ionizing radiation were limited largely to roentgen rays, radium and its disintegration products. The occupational injuries such as radiation burns, ulcers and carcinoma,[1] aplastic anemia,[2] leukemia[3] and radium poisoning[4] were common among the pioneer workers. In recent years these occupational hazards have been reduced but not entirely eliminated by means of education, refinements in technic and a better understanding of the biologic effects of ionizing radiation.

With the installation of cyclotrons in many universities and scientific institutions and the development of the atomic energy industry, sources of exposure to ionizing radiation are increasing with great rapidity. In addition to the increased number of sources, there are the artificial radioisotopes produced by the cyclotrons and the chain-reacting piles that are being extensively distributed for scientific study and therapy of radiosensitive diseases. A hazard of contamination of domestic and wild animal and plant life by radioactive substances will occur if any notable volume of radioactive sewage from industrial and scientific services should develop. Again, if atomic warfare should occur, disposal of radioactive fission products will be impossible and widespread contamination of urban areas and water sheds may occur.

Injuries produced by the new sources and radioactive materials are not different from the injuries produced by the old sources. The problem today is qualitatively the same, but quantitatively there are more persons working with more potent materials. Prevention is the first consideration[5] and recognition of the injury is the second consideration in any program of preventive medicine. The purpose of this report is to outline the available knowledge concerning diagnosis of ionizing radiation injury by means of physical examination, and laboratory procedures. Dosimetry, the basis of prevention, will be referred to only for illustrative purposes.

In the course of this discussion frequent reference to animal experimentation will be made, where human data are lacking or inadequate. It must be fully appreciated, as will be brought out in the course of this report, that the relationship between time of exposure and the appearance of signs and symptoms is not the same for man and smaller laboratory animals. All values for radiation dosage and laboratory procedures are the best possible estimate, based on available knowledge, and will have to be modified as more precise information becomes available.

Both acute and chronic effects may result from either internal or external ionizing radiation. The resulting clinical and laboratory picture is a function of the amount of radiation, its rate of delivery and the depth dosage.[6] This report will be divided into two parts, dealing with the single intense exposure and the repeated exposure of lesser intensity.

### DIAGNOSIS OF SINGLE INTENSE EXPOSURE TO IONIZING RADIATION

For the purpose of the present discussion a single intense exposure will be defined arbitrarily as a total body exposure of more than 25 r delivered within a few hours. An exposure of 25 r is set as the lower limit because the effects of lesser amounts are most difficult, if not impossible, to detect by clinical means.[7] Whether lesser amounts may produce deleterious late effects is not known with certainty. The effect of exposure to ionizing radiation is determined to a considerable extent by the physical characteristics of the ionizing radiation concerned, that is, the type (alpha, beta, gamma, roentgen ray or neutrons), the ability to penetrate (type and energy) and the rate at which the radiation is being delivered. With a single accidental exposure that may occur, these physical characteristics are usually known because of the nature of the experiment. Dosimetry[8] determines to a large extent the aforementioned physical characteristics. These physical characteristics are important because the clinical picture varies with the number of organ systems involved. Total body exposure to highly penetrating radiation in which all organ systems are affected produces the severest picture but with a lesser amount of radiation than larger amounts absorbed superficially.

Symptoms in man following the single intense exposure are well known from the experiences of the Japanese following the atomic bomb explosions over Hiroshima and Nagasaki.[9]

A few hours after exposure to the atomic bomb ionizing radiations, nausea and vomiting appeared. This lasted for a few hours and then subsided for a variable latent period of days. The shorter the latent period the more severe the symptoms of recurrent nausea and vomiting, mucous or bloody diarrhea, purpura, epilation and agranulocytic infections. In general the tempo at which the disease progressed in the Japanese and the Bikini animals was a direct function of the amount of radiation received.[10]

The latent period, the length of time between exposure and the development of symptoms, is of great interest. The duration of the latent period in mammals is inversely proportional to the amount of radiation received. With very large amounts of radiation, in excess of 10,000 r, the latent period becomes short and death may occur within twenty-four hours or even

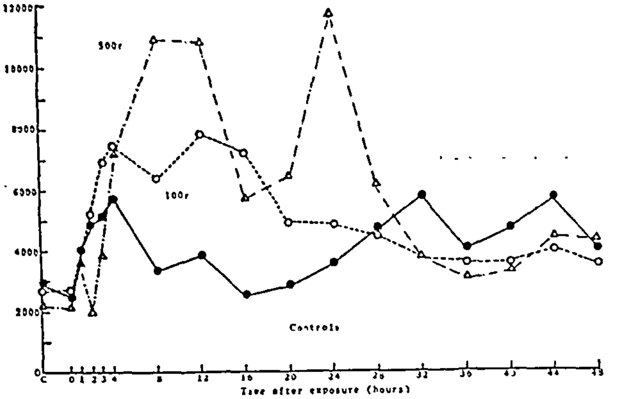
while the radiation is being received.[11] Each species has its characteristic latent period for the development of the full set of symptoms. In goats it appears to be three to five days; in swine it is approximately five to seven days.[10c] In man it is probably longer. It is important to remember that with short latent periods death may occur before the full syndrome develops.



The initial effect (during the first forty-eight hours) of total body roentgen irradiation on the number of heterophils in the peripheral blood. (From Jacobson and others.[7])

In the case of ionizing radiation that can penetrate only a few millimeters of tissue, signs and symptoms are limited to the surface of the body. Raper[12] has described the effects of beta radiation on the skin of rats. Robbins and co-workers[13] have described the effect of scattered cathode rays on the skin of man. In general one can state that the effects on skin resemble thermal burns and that anything from erythema and massive vesiculation to full thickness destruction of the skin may occur. Cutaneous changes are manifested by 1 to 3 stages, depending on the intensity of the radiation. For full details the reader is referred to the articles by Robbins,[13] Raper[12] and Ellinger.[14]

The early hematologic responses of man to single intense exposures to ionizing radiation are not well known. Unfortunately the early blood changes were not observed in the Japanese; hence reference will have to be made to laboratory animals in order to get an idea of what might be expected. There is no reason to expect any qualitative difference, but there may be significant differences in sensitivity and rate changes in the peripheral blood.

The hematologic responses of laboratory animals to single intense exposures to penetrating ionizing radiation are rather uniform.[15] However, after exposure to less penetrating radiation the blood changes may be fleeting, slight or absent despite severe superficial injury.

Beginning shortly after exposure to penetrating radiation, there is a prompt decrease in the total lymphocyte count which is most marked within twenty-four to seventy-two hours, depending on the amount of radiation received[7] (the figure and table 1). Recovery following a nonlethal dose begins within a few hours or days. Developing simultaneously with the progressive lymphocytopenia is moderate granulocytic leukocytosis, which appears as two peaks approximately twelve and twenty-four hours after exposure in rabbits[7] (the figure). If counts are not performed at about hourly intervals one of the peaks may be missed. After the twenty-four hour peak there is a progressive decline in the granulocyte count for the next four to six days, when there is a fleeting increase in granulocytes which is paralleled by a wave of bone marrow activity.[16] This activity is short lived, and the granulocytes again decrease. The subsequent course depends on whether the exposure is lethal or nonlethal. In nonlethal exposures a sustained though small rise in the granulocytes appears around 15 to 17 days. In lethal exposures this sustained return of granulocytes is absent.[10c] Granulocytic leukocytosis may not occur after heavy radiation.[17]

Reduction in the number of platelets and red cells and the morphologic changes in the leukocytes appear more slowly and are not so uniformly observed. In the Bikini goats and swine a pronounced shower of immature red cells appeared in the peripheral blood ten to twelve days after the atomic bomb air burst.[15g] This phenomenon has been repeatedly observed in smaller laboratory animals.[6a] Atypical and immature leukocytes and nucleated red cells appear in the peripheral blood beginning three to ten days after exposure.[18]

In concluding the section of this report on the single intense exposure to ionizing radiation it is felt that the following can tentatively be stated regarding man, until actual observations substantiate or refute these suppositions. If no decrease in the total lymphocyte count occurs in the first forty-eight hours, usually the first twenty-four hours, the exposure has certainly been less than 25 r and symptoms probably will not appear. If exposure has been between 25 and 100 r a fleeting lymphocytopenia will develop and symptoms will prob-

ably be mild. If exposure is between 100 and 200 r the lymphocytopenia will be of greater severity and last longer. Severe symptoms of radiation illness and death will occasionally occur. If exposure is greater than 200 r the symptoms of radiation illness will be much more severe and deaths will occur more frequently. The leukocytic changes, particularly the early lymphocytopenia, will be marked.

The foregoing determination of a decrease in total lymphocytes or total leukocytes unfortunately cannot be predicated on a normal average for man or animals. The range of normal blood cell counts is great for all animals, particularly in mongrel populations like man.[19] Normal hematologic values of man will be considered in the second part of this report along with schemes for the detection of deviation from the normal ranges. Needless to say, in order to detect fleeting changes in members of the leukocyte population total white and differential blood cell counts must be performed every hour or so.

TABLE 2.—*Tabulation of the Variations of the Leukocyte Count of Human Beings with Age* *

| | Number of Subjects† | Age (in Years) | Average in 1,000's per Cmm. | Range |

* From Osgood.[19c]

† Each group included both males and females.

Diagnosis of acute radiation illness by the leukocyte count is obviously totally impractical under conditions of a catastrophe or atomic warfare. Hence the development of an easily read casualty dosimeter is imperative.

## THE DIAGNOSIS OF CUMULATIVE SMALL EXPOSURES TO IONIZING RADIATION

The diagnosis of repeated small exposures to ionizing radiation presents an entirely different problem. The changes are insidious and progressive. If excessive cumulative exposure is not detected early the changes may be irreversible and may lead to serious and fatal diseases.[20] At the present time 0.1 r per day has been set as the maximum amount of radiation that can be tolerated daily with impunity. Animal experimentation by Lorenz and co-workers [21] on mice suggests that the tolerable dose of radiation for females should be set even lower because of increased incidence of ovarian tumors.

The physical characteristics of the radiation determine to a great extent the effects that will appear from chronic exposure. The penetrating radiation may result in generalized systemic and hematologic disorders in addition to the purely superficial effects of radiation with a very low degree of penetrability.

The physical characteristics of the radiation are usually known as a specific job hazard. Relative exposure to beta, soft roentgen and gamma radiation is determined by suitable dosimeters.[8]

The superficial lesions that appear are largely limited to the skin and eyes. Cutaneous lesions are apt to appear in fluoroscopists, radiochemists and radium handlers. An increased brittleness of the finger nails with a tendency for increased longitudinal ridges to develop is common. Later there may be a loss of the integrity of the fingerprint due to patches of atrophy. Pigmentation, ulceration and carcinoma may follow the atrophy. Epilation of hairy parts may occur. Impaired sensation of the finger tips commonly accompanies these changes.[22] In the eyes, radiation cataracts may occur at an early age.[2b] However, the alteration in the blood is the best biologic index of chronic total body overexposure to ionizing radiation.

Many investigators have called attention to the great variability of the blood of man chronically exposed to ionizing radiations. Leukocytosis, lymphocytosis, leukemoid reactions, leukocytic leukemias, erythrocytosis, reticulocytosis, leukopenia, thrombopenic purpura, aplastic anemia and leukopenic leukemias have all been reported as produced by chronic exposure to radiation.[23] The blood picture may be temporarily or permanently altered by many diseases and industrial intoxications in addition to radiation. For example, infectious mononucleosis may affect the total and differential white blood count of young adults for many months after symptomatic recovery.[24] Examples of industrial poisons which affect the blood are benzene [25] and heavy metals.[1] Hence it is apparent that a "normal" range of blood counts for man must be established. This is difficult because the blood picture varies with age and to a variable degree with sex, pregnancy, meals, humidity and temperature.

Osgood [19c] gives the accompanying "normal" values for persons of different age and sex (table 2).

In naval personnel without any recent history or sign of disease [26] between the ages of 17 and 35 in the tropics and in a temperate zone, the total white cell count varied from 4,000 to 16,000. The total lymphocyte count was usually below 3,000 and rarely above 5,000. Probably 90 per cent of the adult population will have total white cell counts between 5,000 and 11,000 per cubic millimeter. The 10 per cent of adults whose counts are outside of this range may cause considerable consternation in a radiologic safety program and lead to medicolegal problems.

Goldwater[25a] has correctly called attention to the wide range of normal lymphocyte counts in his data and those of Osgood.[10c] The data on naval personnel confirm this concept. In addition, Goldwater called attention to the necessity of having comparable parallel control studies on subjects that are not subjected to any known toxic agents.

How are the blood changes of prolonged or repeated exposure to radiation determined? It is apparent that the average count is not dependable for the general population or specific age groups; hence base line complete blood counts must be performed on all persons before exposure takes place. Subsequent counts should be performed at not less than monthly intervals. Notations on the occurrence of colds and infections must parallel the blood records, for without these base line records and a knowledge of each person's response to infections an evaluation of leukocyte changes is more difficult.

A partial review of the literature[27] confirms the opinion that if any of the following alterations are noted in a person whose usual blood values are known and who has been exposed to ionizing radiation it is presumptive evidence of excessive exposure until proved otherwise: (*a*) a persistent depression of the total leukocyte count below 4,000 per cubic millimeter; (*b*) a persistent elevation of the total leukocyte count above 15,000 per cubic millimeter with absolute lymphocytosis; (*c*) relative lymphocytosis with a low total count (4,000 to 6,000 per cubic millimeter) that returns to base line range following removal from exposure; (*d*) an increased mean corpuscular volume (MCV), a shift in the Price-Jones curve to the right, an increase in the mean corpuscular diameter (MCD); (*e*) a reticulocyte count over 2 per cent; (*f*) erythrocytosis: (1) red blood count over 5,800,000 per cubic millimeter; (2) hemoglobin over 18.0 Gm. per hundred cubic centimeters of blood.

Many other phenomena have been suggested as hematologic evidences of excessive exposure. Changes in blood coagulation, prothrombin time, platelets[27i] and morphologic changes in leukocytes[26] have been suggested. It is exceedingly difficult to evaluate the importance and the diagnostic value of these changes. A more recent observation on excessive exposure has been the description of refractile neutral red bodies in the lymphocytes.[23j] These refractile bodies are stained with neutral red in a supravital preparation, and the authors believe that increased numbers of the bodies are specific evidence of exposure to radiation or industrial poisons. The procedure necessitates a flawless supravital technic which is not widely available; hence the technic may not be generally useful. Limited personal experience with swine and goats suggests that these bodies appear irregularly in lymphocytes as the lymphocytes age in the supravital preparations; hence a rigid time control might be necessary.

The foregoing criteria depend on abnormalities in the enumeration or morphology of blood cells which arise from either depressed hemopoiesis, an increased lability of the hemopoietic organs or abnormal maturation. The establishment of the presence of these criteria must of necessity be done without adequate controls, which would not be permitted in the average biologic experiment. Hence it is much better to have some type of human control. This can be attained by establishing a comparable control group which are not subjected to any known toxic agent and performing parallel studies on this group. Average values for exposed and control groups should be studied statistically to see whether there are significant differences between the means of the two groups. In a comparable fashion the preexposure counts of the exposed group can be used as the control. If the average leukocyte count of the group for a given exposure period is significantly less than the group average leukocyte count of the preexposure period one can state with considerable certainty that excessive exposure to ionizing radiation or other toxic agent has occurred.

The following procedures will aid in determining the cause of any abnormal blood findings in a person suspected of having been excessively exposed: 1. Remove the suspect from all possible exposure to ionizing radiation. 2. Do differential counts of radiation on excreta, nasal swabs and expired air in order to estimate the type and degree of internal exposure to radioactive isotopes. 3. Study the blood at weekly intervals and compare with the preexposure base line leukocyte counts and search for an increase in the number of highly refractile, neutral red bodies in the lymphocytes. 4. Endeavor to eliminate other factors such as infectious lymphocytosis, infectious mononucleosis, virus diseases, benzene poisoning and heavy metal poisoning.

## SUMMARY AND CONCLUSIONS

The diagnosis of a single excessive exposure to ionizing radiation by blood examination is not difficult. If serious exposure has occurred, prompt, marked lymphocytopenia results and is followed by a characteristic sequence of events in the other members of the leukocyte population.

The diagnosis of repeated exposures to small amounts of ionizing radiation in a person is much more difficult and uncertain. It requires, in addition to blood studies, differential counts of radiation in urine, feces and nasal secretions and, lastly, the elimination of other industrial hazards.

The determination of repeated exposure to small amounts of ionizing radiation in groups of personnel by the statistical comparison with a control group or by statistical comparison of the average leukocyte count before and after exposure is a reasonably accurate diagnostic procedure.

The main bulwark of protection from ionizing radiation must remain physical control of radiation intensities by established monitoring procedures and prevention of contamination of personnel by radioactive materials. This is essential, because most of the signs and symptoms appear relatively late after the radiation injury has been sustained.

**Penicillin and Bacterial Endocarditis.**—Loewe deserves great credit for having demonstrated the value of large doses of penicillin in this disease after the Penicillin Committee had officially declared it to be of no value. Following his reports of cures after using quantities of penicillin far larger than had previously been tried, success was achieved almost uniformly, and today it is possible to state that the great majority of patients with this infection can be cured if sufficient amounts of penicillin are administered.—H. # HEALTH OF THE NAVAJO-HOPI INDIANS

### General Report of the American Medical Association Team

LEWIS J. MOORMAN, M.D.
Oklahoma City

NOTE.—*The following special report on medical conditions among the Navajo-Hopi Indians was made by a group of physicians who were sent by the Department of the Interior as representatives of the American Medical Association. The arrangements were made by a committee of the American Medical Association, which is advisory to the Honorable J. A. Krug, Secretary of the Interior. The team comprised Dr. Samuel Ayres Jr., Los Angeles; Dr. A. A. Thurlow, Santa Rosa, Calif.; Dr. Harold E. Crowe, Los Angeles; Dr. Louis C. Ruschin, Oakland, Calif., and Dr. Lewis J. Moorman, Oklahoma City, Chairman. This project was approved by the House of Delegates of the American Medical Association.*—ED.

> I come to show you sweet Caesar's wounds; poor, poor dumb mouths, and bid them speak for me.—Mark Anthony.

## HISTORICAL BACKGROUND[1]

In 1868 at Fort Sumner, the United States, entering into a treaty with the Navajo Indians, exacted submission with definite promises from the Navajos based on government performances made obligatory in terms of the treaty.

The Navajos promised to remain on a reservation and to compel their children to go to school. The United States agreed to provide a teacher and a schoolhouse for every 30 children between the ages of 6 and 16 "who can be induced or compelled to go to school." Coincidentally with education the necessity of economic rehabilitation was recognized by the government. Apparently nothing was said about medical care, without which neither of these treaty objectives can ever be fully realized. When mutual promises were consummated and signatures affixed, the government planted the Navajos on the present reservation without reckoning with the exigencies of the forbidding terrain. The dependence on their herds and the sparsity of herbage inevitably made nomads of the Navajos and kept them on the move, threading ancient arroyos, wading sand dunes, scaling bluffs and unobtrusively blending with sage and sheep on lonely mesas.

On 18,000,000 acres of the world's proving ground for erosion, the Navajos are still tucked away from civilization with two and a half square miles for each hogan. Many of them are isolated by the absence of roads and periodically cut off by sand blows, flash floods, snow storms and mud holes and often by the mere penalty of dire remoteness. Ultimately this remoteness caused the government to realize that the Navajo child must be located and transported to a schoolhouse or the schoolhouse brought to him before he can be educated. The treaty still stands. The Navajo people are now willing to send 24,000 children to school, but the government, in approximately 80 years, has provided schools for only 8,000 children, and after all this time only 20 per cent of the Navajos speak English. Economic rehabilitation has suffered the same fate. Because of a tardy consciousness of medical needs, the Indians' health has fared no better than education and economic competency. In fact, the incidence of some preventable diseases, such as tuberculosis and venereal diseases, is increasing. Vaccination against smallpox and typhoid has proved a great boon. This is not intended as an indictment of the administration of Indian affairs, but a brief enumeration of some of the past and present difficulties, including the almost insurmountable physical handicaps. In spite of all these obstacles the Navajo flocks multiplied, and in the face of a high infant mortality, carrying out the ancient law "the survival of the fittest," his people have increased from 8,000 to 64,000 in less than two generations. Through curtailing the seeding of the native grasses through increase in his flocks, he was impressed with the necessity of animal procreation and made the most of it among his flocks and in the hogan.

His unusual fecundity, possible based on his heterogeneous origin, "hybrid vigor," influences of the desert, his pertinacity, his poise and his hard-earned psychologic self sufficiency, indicates that he may make a valuable contribution to the white man's culture and slow his frenzied mechanistic marathon to a more reasonable pace.

Apparently the first recorded appropriation of funds for medical care of the Indians was on a California reservation in 1856. In 1857 a hospital was established in Northern California and a physician employed. With this exception, especially in the Southwest area, physicians, when employed, were charged with the care of Indian agents and their families and employees. But even this service was not provided before the 1870's. Three or four physicians were appointed as Indian agents in the Southwest, and they must have mixed medical care with administrative duties. In 1873 a medical and educational division was established in the Indian bureau. This, however, was abolished in 1877, in spite of great demands for medical service. Even under this provision only about one half of the agencies had been provided with physicians. Certainly this was true in the Southwest. For a long time the Navajos had only one doctor to serve 15,000 to 20,000 persons.

By 1878 the Commissioner of Indian Affairs decided that persons employed as physicians on Indian reservations should be "graduates of some medical college and have the necessary diplomas." He had the good sense to add that because of the character of the so-called physicians serving the Indians they had lost "faith in the superiority of the white man's medicine and returned to their former methods of curing the sick."

There was a gradual awakening of the Government with reference to medical care for the Indians in the first and second decades of the twentieth century. But two world wars have made it difficult to secure the services of good physicians and have decimated the supply of nurses. In spite of the best intentions and much good work on the part of many conscientious administrators, the results are unsatisfactory. More than any other people in the United States today the Navajos need patient sympathetic understanding of both body and mind to win them from the machinations of the medicine man, whose three to nine day "sings" and "dances" are not limited by hourly schedules and do not click with the clock. It will require genuine patience and devotion to meet the medicine man's intensive psychotherapeutic appeal, especially until general education brings more light.

---

. This report was made in collaboration with other members of the team.

[1] The essential facts in this historical sketch are gleaned from Dale, E. E.: Indians of the Southwest: A Century of Federal Relations, chaps. 13-15, to be published.

## A BRIEF SUMMARY OF THE TEAM'S OBSERVATIONS WITH RECOMMENDATIONS

> In our Century science is the soul of the prosperity of nations and the living source of all progress. Undoubtedly the tiring discussions of politics seem to be our guide—empty appearances! What really leads us forward is a few scientific discoveries and their application.—Pasteur.

This statement is based on individual studies and a careful perusal of the reports presented by the other members of the team.

On the whole it may be said that all the members of the team are in accord on all the observations, questions, problems and recommendations in this report.

The diseases afflicting the Navajo-Hopi Indians with few exceptions differ from those found in the white population only in degree, and this difference is due to environmental conditions, want of education and adequate medical care rather than to innate racial factors and influences.

For example, the meager statistical data regarding tuberculosis indicate that the mortality from this disease is approximately 10 times that in the general population. Yet its course in the Indian closely parallels that in the white man. This being true, we must conclude that the difference must be due to provocative factors in the environment, including faulty nutrition, physical hardships, overcrowding in the hogan and inadequate medical care, which implies the lack of effective case finding, the failure to break contacts, imperfect methods of management and the lack of sanatorium care with all the modern phases of collapse therapy and eternal vigilance through adequate follow-up service.

The same may be said of the upsurging venereal diseases, particularly syphilis, since the last war, and the same is true of the preventable killing diarrheas crowding the hospitals with children in certain seasons. Trachoma, which might be eliminated by an intensive treatment campaign, continues to take its toll. The one time Indian service physician, Dr. Lowe, should have credit here for discovering the cure for this condition.

There are many other medical, surgical and orthopedic conditions as well as dental problems. On the reservation there are communities where congenital hip is prevalent. Here early advice might save crippling for life.

These few examples suffice to show what goes on and to justify our recommendations in behalf of a fine race of people who have contributions to make to our culture and to justify what we would designate as ultimate economy through the immediate expenditure of large sums. We must protect the well by preventing and curing disease in this hotbed of uncontrolled communicable conditions. Citing a ridiculous example for emphasis, it seems the irony of fate that in this day of DDT and other agents with which to combat infestation, the teachers must go through the disgusting discipline of delousing the pupils every time the schools open and repeatedly when children are permitted to return home. Adequate health education and field service under medical supervision should take care of this as well as many other more serious evils.

The common preventable, communicable and curable diseases and conditions are being stressed in this report because they best reveal the inadequacy of past and present medical services. Other preventable conditions which go unchecked to dog the Indian's existence are pediculosis (lice), scabies (itch) and nutritional deficiencies. We realize that the Indians are subject to the average run of the diseases which afflict other races, but it seems unnecessary to enumerate them in this abbreviated report. Enough has been said to reveal certain defects, to justify what may seem to be rather radical recommendations. While looking into the Navajo's way of life and recommending the white man's culture and mode of living, we are forced to wonder what we might gain if we were willing to learn.

They seem to do very well on a rather simple limited diet. Compared to our general population they are virtually free from cancer and diabetes and they have a very low incidence of heart and blood vessel disease (arteriosclerosis). Among our people these three conditions are on the increase and contending for first place in mortality statistical columns. Perhaps the limited diet, the slow pace and the desert poise have much to do with this interesting disease discrepancy. No doubt the ratio will change as we continue to give them syphilis, gonorrhea, "firewater," soda pop, candy bars and spearmint.

### OBSTACLES

> Great works are performed not by strength but by perseverance.—Samuel Johnson.

While the obstacles are great, they seem not to be insurmountable. On the contrary, they present a commanding challenge.

Among the natural physical handicaps which to some extent explain and excuse the failure of the Indian service in the field of medicine are: the forbidding terrain and the almost inaccessible remoteness of many of the Indian families and communities. Naturally, this implies the need of better roads with adequate means of transportation, including the possibility of emergency air ambulance service. As explained elsewhere, the Indians on the Navajo Reservation became nomads through the force of circumstances. The life of the nomad in the desert is incompatible with adequate medical supervision and control. Even the faulty nutrition due to limited food supplies is a necessary result of the unaided nomadic existence, and it is difficult of solution. The inadequate, inaccessible, unsanitary and impure water supply constitutes serious health hazards. Among other immunity procedures, typhoid vaccine has helped to obviate one of these hazards. No doubt, few persons know that often the Indians are dependent on temporary water holes for drinking water, which is sometimes thick enough because of yellow mud to make good topsoil. How slowly we learn. Aristotle told Alexander the Great, "Do not let your men drink out of stagnant pools. . . . Athenians, city born, know no better; and when you carry water on the desert marches, it should be first boiled to prevent its getting sour."

Among the innate psychologic and spiritual obstacles are the profound attachments of the Navajos to their mother earth, which in their opinion gave birth and ultimate haven to not only their gods but to them and their children as well. Of equal importance is the fact that their religion is their medicine and vice versa, making their medicine men the exponents of both. Naturally it is difficult to move them off their beloved land and even more difficult to induce the illiterate (non-English-speaking 80 per cent of the Navajos) to discard their native medicine (religion) in favor of the white man's medicine. Though we question the efficacy of the medicine man's way of employing a few herbs and singing, dancing and drumming the evil spirits away, we must admit that compared with the methods of modern medicine the constant presence of the medicine man and his untiring ceremonial devotions for days and nights have a profound psychologic influence.

We cannot pass on without mentioning the psychologic impact of administrative errors, whether inevitable or otherwise, and misunderstood administrative orders and regulations, whether obviously beneficial or based on the law of trial and error with well founded hope. Everywhere we were assailed by the evidence of disturbed psychology and lack of faith on account of the "sheep and goat reduction program." Though unqualified to pass on the merits of this program, we could not escape the unfortunate reaction and disturbed confidence because of this control measure which did work an immediate hardship on some families. The well meaning attempt to make available community day schools and the enforced nomadic movement away from such schools for better grass, leaving them empty, furnishes another example of natural difficulties and resulting unfavorable psychology. This naturally poses the question of linguistic difficulties, which are so obvious it seems unnecessary to devote more space to them. These difficulties and the crying need of economic rehabilitation only serve to emphasize the need of an intensive general educational program.

On the Hopi Reservation we found the schools well attended, one accommodating the Walpi area having the highest record of attendance in the United States, the children relatively well nourished and 80 to 85 per cent of the people speaking English and liking it. The Hopis are better housed and living in villages under better sanitary conditions than the Navajos. They live both by animal husbandry and agriculture and produce some fruits. Consequently, they are not so apt to suffer nutritional deficiencies. Perhaps they are more ready to cooperate, to follow advice, rules and regulations. This may be accounted for by such factors as the high percentage of literacy (English) and the fact that they live in villages (more accessible, etc.). The medical and public health services at, and emanating from, the hospital at Keams Canyon are relatively good. Since the Hopi Reservation, containing only 4,200 Indians, rests like an island in the Navajo Reservation, we wonder whether separate administration of its medical services under the proposed plan should not be considered an obstruction to efficiency and economy.

Among the obstacles wholly under the control of man may be mentioned certain deficiencies and defects in the field of physical facilities, health administrative offices, professional personnel, housing, hospitals, sanatoriums, health centers and equipment.

Obstacles arise through quantity, character and scientific quality of professional personnel. As stated elsewhere, the government or particularly the Office of Indian Affairs may not altogether be responsible for shortages and defects in this field. The impact of two world wars, the changes in medical and hospital practices and patient psychology throughout the United States have made it ever more difficult to secure competent physicians, nurses, public health, social service, rehabilitation, welfare and health educational workers.

Unfortunately, the supply of physicians for the Indian Service is influenced by unwarranted restriction which must have consideration. In the Oct. 16, 1948 issue of *The Journal*, this headline appeared: "The Government Needs Physicians." Time and space will not permit a full quotation. Suffice it to say that the appeal comes from the United States Civil Service Commission and that among positions to be filled are those in the Indian Service. Significantly, from our point of view, the salary range is from $4,479 to $6,235. Only those who have had professional experience can hope to start in one of the brackets above the $4,479 figure. The maximum age limit is 50 years. A long discourse on relative wages and salaries and the present high cost of living would be out of place, but those who read this report are requested to take into account the fact that a physician qualified to cope with the exceptional medical, surgical and public health difficulties presented here will have spent eight to twelve years in the most exacting and the most expensive existing educational adventure. This means that he has spent a small fortune and given up a goodly number of his productive years in order that he may make a genuine contribution in an important field of human weal. Certainly he would not work for money alone after such a grueling educational experience. But he must have a reasonable competency while he pursues his professional duties even though he works chiefly for the love of accomplishment. Nothing short of this can ever redeem the Navajo health situation. We humbly inquire, What can the Indian service expect on $4,479 a year? A job at a gasoline station before embarking on a professional education might promise more.

Before leaving this question of professional personnel, the matter of nonprofessional administrative influences causing delays, limiting initiative and occasionally leading to unwarranted control of employment, tenure of service and expenditure of medical appropriations, must have serious consideration by all who are interested in the solution of the existing medical service problems. While we admit the omission of much meaty material, we feel that the aforementioned factual data are sufficient to make a case and to warrant the following recommendations.

### RECOMMENDATIONS

> The legitimate object of government is to do for a community of people whatever they need to have done but cannot do at all or cannot do as well for themselves in their separate and individual capacities. In all that the people can do as well for themselves the government ought not to interfere.—*Lincoln.*

The team, after traveling over the Navajo-Hopi reservations working day and night for the purpose of inspecting and studying health conditions and existing health facilities and considering the unmet medical needs of the Navajo-Hopi people, came together at Winslow to round out the two weeks' survey with an all day conference. This resulted in a free discussion of observations, impressions, convictions and conclusions. All these were given careful consideration and ultimately integrated, correlated, unified and crystallized into a creed which, in our opinion, warrants the following recommendations.

In keeping with a previous discussion of the Hopi situation in relation to the encompassing Navajo Reservation and in order that the Hopi health service may be included, we recommend that the Director of Health, Office of Indian Affairs in Washington, the District Medical Officers, Staff District IV and the Chief Medical Officer at Window Rock consider the feasibility of a unified medical service for the Navajo-Hopi Reservations.

Since the Health Service cannot possibly hope for a full fruition with intelligent cooperation and a certain degree of economic competency on the part of those who are being served as long as only 20 per cent of them speak English we recommend an intensive comprehensive program in general education. Since the reports indicate that there are 24,000 children of school age with school facilities for only 8,000, the opportunity is obvious and the need imperative. Furthermore, our treaty obligation stands as an embarrassing challenge. We take space to add that the attitude of educated Navajos and their ability to acquire skills and to develop economic resources are most encouraging. More intellectual light in connection with the medical program is badly needed.

It is the unanimous opinion of the medical team that the desired evolution of what amounts to almost a medical miracle cannot be realized under the present administrative methods. As we see the situation in the light of past accomplishments and present handicaps, only complete professional autonomy can accomplish satisfactory results. The Chief Medical Officer should be free to make plans, build budgets and make and act on decisions having to do with the welfare of his charges. He should have full charge of the medical service appropriations, the employment of professional personnel and the tenure of service. He should have proportionate office space and personnel and personal housing to meet the needs of an expanding service. He should be free to project and plan hospital and clinic buildings and to recommend location, construction and equipment. We recommend professional autonomy and an entirely separate health appropriation to be controlled by and spent for the health division.

The aforementioned long term formal educational requirements for physicians would seem to make autonomy obligatory. No other department on the reservation, not excepting education, requires so much in the way of preparation. No other service carries so much responsibility. Decisions having to do with birth, health, life and death must be in the hands of the physician; only he can justly carry the responsibility. Good physicians cannot afford to serve without initiative and freedom of action.

Though the government is bound by approximately 5,000 treaty obligations and statutes, apparently it is free to provide complete professional autonomy in the administration of medical care.

This leads to a recommendation that the Indian medical service be freed from the handicaps inherent in the Civil Service regulations, including salary and age limitations.

The Navajos sent a larger percentage of their total population into military service and war work than did the white people of the United States. It is believed that those that survive the high infant mortality and escape tuberculosis should make a good showing at the induction centers. The Navajos are anxious to make good citizens; they are entitled to the best. The best physicians are not to be found in the Civil Service supply. Those who doubt these statements are requested to check this source of medical personnel. With freedom from salary restrictions, we recommend that the Chief Medical Officer should be promptly endowed with authority to build adequate administrative, hospital, clinical and field staffs. In the administrative office he should have an Assistant Chief Medical Officer, a statistician (for the first time the present Chief Medical Officer has established and filled this position). He should have other necessary office personnel to negotiate adequately the important functions of his office and to keep the Washington office thoroughly informed as to his activities and statistical results. Only through such a service can those in the central office keep a level gaze on the administrative and field operations on the reservation, and only through such knowledge can representatives in the Washington office act intelligently. We recommend an adequate statistical service in the health divisions on the Reservation and in Washington through which all morbidity, mortality and other vital statistics may be tabulated, correlated and made available for the benefit of the service and to encourage clinical research.

In order to cover adequately the immediate needs of the Navajo-Hopi Medical Services, we recommend that the Office of Indian Affairs consider the construction of a medical center, at a rail head, possibly at Gallup or Winslow, with capacity to serve as a clearing house for all diagnostic problem cases, all major medical and surgical cases requiring expert services and special skills, possibly with the exception of thoracic surgery, which might be more profitably based at the present Medical Center at Fort Defiance.

The present hospital at Fort Defiance, now known as the Medical Center, should be converted to, and utilized in, the big task of providing sanatorium and hospital beds, comprehensive and diagnostic service, expert medical and surgical treatment for tuberculosis. Those who may not understand the significance and magnitude of this problem should read the individual report on tuberculosis.

It is believed that such a plan for expansion will be necessary to meet hospital needs, especially with the development of adequate field service and case finding. While immediately expensive it will result in the saving of life and ultimately prove to be economical.

The Medical Center should serve all outlying districts through cooperation with their hospitals and coordination of their work, through field service to be developed and through a case-screening service to be practiced in the district hospitals and health centers.

In addition to Fort Defiance, there are now four hospitals serving the Navajos and one on the Hopi Reservation serving both Navajo and Hopi. Three formerly in operation are now closed, and it is recommended that they not be reopened because of location, physical conditions and the proposed new plan.

The diagnostic, medical and surgical services in the outlying hospitals can be improved, but probably never brought to a high degree of scientific efficiency. At present the most satisfactory medical services in these district hospitals are to be found at Crown Point and Keams Canyon (Hopi).

The shortcomings in these hospitals can be largely compensated by the proper development of the proposed Medical Center and also the clearing of difficult cases through the health centers, some of which might otherwise reach these hospitals.

Though there are now three or four field nurses, there are no health centers or, perhaps better termed, field units in full operation. It seems reasonable to recommend at least four such units to meet immediate needs:

1. Shiprock, with three nurses
2. Fort Wingate, with three nurses
3. Tuba City, with two nurses
4. Chinle, with two nurses

Each of these units should have a physician (Medical Officer), a dentist, nurses, a sanatarian and a clerk. The difficulty in securing personnel willing to remain in some of these remote areas is significant. Perhaps a rotating service would help solve this problem.

The social and shopping isolation and the housing and living conditions on the reservation demand careful consideration. They definitely affect salary considerations. Some of these difficulties would be overcome by the proposed location of the Medical Center. Plans for time off, transportation and recreation for those in the more remote sections must have attention before good work and satisfactory tenure of service can be expected.

The success of these plans will primarily depend on proper professional personnel. As in the Veterans Administration chief hospitals, we feel that the medical staff at the Medical Center should be of such a caliber and the hospital and the equipment of such a character as to qualify for intern service. With this in view, we also recommend a visiting consultation and teaching service through one or more university medical schools.

Without these essentials, well qualified young physicians cannot afford to accept service on the reservations and a fertile field for valuable research will remain untilled. It will be most unfortunate if the rich opportunities in medicine, surgery, nutrition and degenerative diseases and others are not made available through execution of the plans proposed by the team.

We recommend frequent clinical and pathologic staff conferences at the Medical Center, with emphasis on educational values; as far as possible such conferences should be attended by the professional personnel at the outlying hospitals and health units.

We recommend staggered leave of absence for faithful professional personnel at the discretion of the Chief Medical Officer for graduate work in accredited clinics, hospitals, laboratories and foundations.

In our opinion the following services or departments should be considered essential, the heads of which should be qualified by training and experience in their respective fields and preferably certified specialists or of comparable standing and ability.

1. Internal medicine
2. General surgery
3. Pediatrics
4. Obstetrics
5. Diseases of the chest
   (*a*) An internist with special training in diseases of the chest
   (*b*) A thoracic surgeon who will also do bronchoscopic work
6. Orthopedics (While we have no accurate statistics we were told that there are 500 crippled children on the reservation. This may have included the unusual number of congenital hip cases in certain districts)
7. Ophthalmology and otolaryngology
8. Dermatology and syphilology
9. Neuropsychiatry
10. Pathology
11. Roentgenology
12. Laboratories with necessary qualified technicians

It was thought that possibly thoracic surgery, the dermatology and syphilology and the neuropsychiatric services might be placed on a contract basis, at least temporarily.

In connection with these plans, we can visualize an affiliation with public health schools and public health nursing schools for special training in field work. No comparable opportunity is now available anywhere in the United States. Likewise, we are thinking of training schools at the Medical Center for Navajo nurses, Navajo nurse's aids and aids for health education, social service, rehabilitation and welfare workers. The transition from desert Bedouins to useful citizens can be definitely accelerated by the use of such Navajo aids.

To make the plan function satisfactorily, transportation must be developed. We recommend more and better roads, and we suggest serious consideration of strategic air strips and air ambulance service for emergency cases—this either through government-owned planes or through contract service.

We recommend full cooperation with the surrounding state health departments in all matters of public health, including a statistical exchange service in connection with birth, communicable disease, morbidity and mortality statistics.

The team had conferences with tribal council members, educated (English speaking) teachers, traders, missionaries, Navajos and medicine men. After carefully weighing the results, we seriously considered the feasibility of a tactful approach designed to gain the confidence and cooperation of as many of the medicine men as possible and the advisability of bringing them into the medical center for a better understanding of the white man's medicine. It was thought that visual comprehension of what medicine and surgery can do and simple instruction might help obviate the danger of delay caused by prolonged ceremonials when there is dire need of hospitalization. Peritonitis from ruptured appendix and moribund babies from summer diarrhea serve as outstanding examples of disaster through such delay. The educated Navajos think the medicine man is on the way out, but much harm may be done while we supinely await his passing. We found two, a medicine man and a medicine woman, in hospital beds gladly receiving the white man's medicine. We talked to another who came to the Crown Point hospital purposely for a conference with representatives from the white man's American Medical Association. He wanted better hospital services for his people and revealed that he harbored certain pet peeves because physicians previously on the hospital staff did certain things without taking time to explain why and because postmortem examinations were performed without consent and without an explanation of what was found. This latter discussion came about in response to a question as to whether the medicine man would approve of postmortem examinations with the hope of learning how to help those still living. It is our belief that the Indians want to cooperate and that we have not fully measured up to our opportunities and our obligations.

The members of the team feel that the acceleration of education, with the hope of removing linguistic difficulties, that the coming of the franchise and participation in all federal and state benefits should make personal responsibility for medical care, except for the indigent, a valuable factor in the plan for "economic rehabilitation."

Regardless of the plan adopted, we recommend that the government should gradually move away from the debasing influences of all unnecessary paternalism and, through the elevating influences of education and economic competency, strive to engender the coveted consciousness of self sufficiency. The Great White Father, George Washington, once said, "He who seeks security through surrender of liberty loses both."

### A BRIEF OF RECOMMENDATIONS

1. Unified medical and public health service for the Navajo-Hopi reservations under direction of one chief medical officer.
2. General education should be assiduously pursued until every Navajo speaks English. This is a prerequisite to the development of an adequate medical program.
3. Complete professional autonomy, giving the chief medical officer full control over the medical service.
4. Freedom from Civil Service salary provisions.
5. Salaries for physicians in keeping with training, ability and highly specialized skills.
6. The establishment of a new medical center to meet the requirements of an adequate health service for the Navajo-Hopi reservations.
7. A hospital and medical staff which can qualify for intern service and stimulate research. A consultation visiting service should be established with accredited medical schools, and all possible educational advantages should be made available to the in-service professional personnel.
8. The Office of Indian Affairs should consider the feasibility of employing the proposed medical center as a clearing house for all cases from other Indian reservations in the Southwest presenting diagnostic and therapeutic problems requiring highly developed skills and technics.
9. Schools should be established at the medical center for the training of Indian aids and interpreters to supplement the services of doctors, nurses and workers in all departments where such aids can facilitate progress in their respective fields and help bring about the gradual transition from tribal dependency to individual citizenship with its opportunities and obligations, including the privilege of paying for medical care.
10. An immediate comprehensive case-finding program in the field of tuberculosis. Provision for all cases discovered. BCG vaccination of all persons not sensitive to tuberculin. Adequate social service, health education and rehabilitation in this field.
11. The conversion of the present medical center to what might be called the tuberculosis control center or the sanatorium center. Inexpensive beds should be added as needed to give the best of management in every case discovered.
12. The Chief Medical Officer should be authorized to organize and implement adequate health field services including the establishment of field units.
13. Adequate vital statistical services should be established in the Washington Office of Indian Affairs and in the various regional offices in order that policies and practices may be intelligently conceived and implemented and research in various fields encouraged through the aid of statistical studies.
14. The Washington office and Congress should give careful consideration to the unusual opportunities for sustained and controlled research in certain important phases of medicine now posing serious questions. Among these are: 1. The surprising nutritional responses to what seems to be qualitatively and quantitatively an inadequate diet wanting in variety according to accepted standards. 2. The low incidence of degenerative cardiovascular conditions, including coronary and cerebral accidents in connection with these dietetic limitations, habitat and environmental factors. 3. The very low incidence of cancer and its possible relationship to diet. Dr. Salsbury at Ganada Mission Hospital reports only 36 cases of malignant conditions, all types, in 30,000 admissions. In the same number of white persons he should have found approximately 1,800. 4. Diabetes is apparently very rare. A study of the relationship to diet and mode of life would be interesting. Dr. Salsbury reports 5 in 25,000 cases studied. In that many white persons we would expect 75 times that number. 5. The apparent absence of and lack of susceptibility to scarlet fever poses an interesting question. 6. The unusual frequency of congenital hip in certain areas arouses scientific curiosity in this inherent biologic or hereditary phenomenon. These are only a few of the untouched possibilities awaiting the clinician and the research worker in this fallow field.
15. The individual reports prepared by the members of the team should be carefully studied by all who must assume the responsibility of planning and implementing the medical program.

## SUPPLEMENT TO THE AMERICAN MEDICAL ASSOCIATION TEAM'S REPORT

The following excerpt from Sigerist's review of Jacques Schwetz's book,[2] seems to have significant application to our study of the health situation on the Navajo-Hopi reservation. It gives a graphic picture of the development of health services in Belgium's African colony and contains so much of interest in connection with our study that it seems at least worthy of the team's consideration and may be considered helpful in the interpretation of the team's report.

In 1885 the Congo Independent State was founded by Leopold II, King of the Belgians, and was placed under his sovereignty. It was annexed to Belgium and became a colony in 1908. In the beginning medical services were completely haphazard. A few dozen doctors of all nationalities without special qualifications were hired. Their function was to look after the white people and the Negro soldiers in the centers. Then from 1908 on, after the country had become a colony, services were gradually organized and steadily improved. Sleeping *sickness gave the chief impetus, since it deprived the colony* of native labor. The Negroes attributed the disease to the coming of the white man, a suspicion that was not without justification. The white man neither brought the tsetse fly nor the *Trypanosoma gambiense* but he greatly increased the traffic between the various sections of the country, so that the ever present flies had many more opportunities to become infected and to spread the disease.

This is not the place to describe the heroic fight against sleeping sickness and malaria to which the author devotes more than half of his publication. It was a fight in the course of which the colonial government developed a system of social medical services which in many ways was more complete than that of most European countries, a system that emphasized prevention rather than cure. In the beginning the physician was completely subordinated to the colonial administrator, so that he was entirely at his mercy, but later a special medical administration was inaugurated with a physician-in-chief at the head of the services of the entire colony, physicians in charge of the 6 provinces and others directing the services of the 16 districts. Laboratories were erected in every province and numerous schools were created for the training of native auxiliary personnel, an extremely important measure. Indeed, one does not need a licensed physician to distribute quinine or to immunize people against cholera. With adequate auxiliary personnel a physician can increase the radius of his field of action many times. Dr. Schwetz also very correctly points out how fatal perfectionism is in such matters. Physicians, of course, should be as well trained as possible, and it was a great step forward when all physicians going or returning to the Congo were required to take a course at the School of Tropical Medicine in Brussels. But auxiliaries should not be half-baked doctors, and if requirements are too high there will either be not enough students or those who do qualify will not be satisfied with the status of a mere auxiliary. This experience has been confirmed in other colonies. . . .

Dr. Schwetz is very critical of red tape which cannot be eliminated but should be reduced to a minimum, of window dressing, and of administrative megalomania, a well-known colonial disease which invariably affects certain individuals who at home would be nobody and in the colonies suddenly attain the status of a sultan. Dr. Schwetz can afford to be critical because he is well aware that Belgium has done a splendid job of social medicine in the colony. Nothing could testify for it better than the changed attitude of the natives toward modern medicine. Formerly when the doctors came to a village with puncture needle and microscope looking for early stages of sleeping sickness, the population vanished into the bush or the chief declared categorically that they refused to be pricked with needles which were the cause of the disease.

---

[2] Schwetz, J.: L'evolution de la medecine au Congo belge, Université Libre de Bruxelles, Institut de Sociologie Solvay, Actualités Sociales, Nouvelle Série. Bruxelles: Office de Publicieté, S. G., 1946, 132 pp., reviewed by H. E. Sigerist, Bull. Hist. Med. **22**: 358 (May-June) 1948.

Today they seek the doctor spontaneously; they have realized that the wihte man is not only a collector of taxes, and they have confidence in the physician. . . .

I often wonder whether health conditions in tropical Africa are so much better today than they were before the advent of the white man. The Negroes must have developed their immunity against malaria long ago. Sleeping sickness was limited to certain regions. There was some leprosy, to be sure, Bilharzia, worm diseases, dysentery. They probably had more food and a better diet than they have now, and their witch doctors must have had good results in a number of cases. They certainly gave more and better psychiatric services than the whole of Africa has today. Then the white man came, took land away from the natives, forced them to do wage work, taxed them, upset their cattle economy and replaced it by a money economy which is hard for them to understand, spread syphilis, alcoholism and many other diseases. The social, economic and moral balance of entire populations was destroyed, and this obviously affected the people's health adversely. And then the white man seeing that he was losing the chief wealth of his colonies, the labor power of the people, developed health services and did it sometimes very successfully as we have seen in the case of the Belgian Congo.

Detribalization, education, the modernization of agriculture and the development of some industries are unavoidable if the standard of living of the African population is to be raised; it cannot be done, however, by an exploiting minority but only by the people for the people.

# Clinical Notes, Suggestions and New Instruments

## NEPHROSIS OCCURRING DURING TRIMETHADIONE THERAPY

### Report of a Case

JOHN C. WHITE, M.D.
New Britain, Conn.

In May 1948, Barnett, Simons and Wells[1] reported a case of a 16 year old patient in whom the manifestations of a nephrotic syndrome appeared while the patient was taking trimethadione ("tridione"). Certain features of the patient's course and condition seemed to differ from the clinical picture of nephrosis resulting from poisoning or occurring spontaneously from unknown causes. The nephrosis occurred during the administration of the drug, disappeared after the withdrawal of the drug, recurred when the medicine was exhibited again and again disappeared after withdrawal of the medicine. Moreover, the patient at the height of her nephrotic state showed intense proteinuria, hypoproteinemia, hypercholesterolemia and yet practically normal renal function. The authors found it probable that there was a causal relationship between the treatment with trimethadione and the appearance of the nephrosis. Nevertheless, they state that "final evaluation of the relation of tridione to the nephrotic syndrome must await further observations in this and other patients." Many of the details of the following case history closely parallel the experience reported by Barnett and his co-workers.

### REPORT OF A CASE

In 1935, at the age of 7 years, J. P., a white boy of Jewish parentage, was admitted to the New Britain General Hospital with fever and headache, and, after a brief illness diagnosed as polioencephalitis, he recovered with a residual weakness of the right side of the face. In 1939 he was again admitted to the hospital with clinical laboratory observations which led to the diagnosis of lymphocytic choreomeningitis. He recovered from this without apparent residue, but in June of 1947 he began to have seizures. These seizures were described as a feeling of being cut off from his surroundings. Without dizziness or tendency to fall or faint, he nevertheless felt as if he were walking on a pillow, or on air, and sometimes believed that he was aware of an odor which he never has identified. After three such spells had occurred the patient was examined by a consulting physician, who reported that there were abnormal electroencephalographic observations that were indicative of idiopathic epilepsy. On June 14, the patient commenced taking diphenylhydantoin sodium ("dilantin"), 1½ grains (98 mg.) three times a day, and trimethadione, 3 grains (195 mg.) three times a day. Shortly after this therapeutic regimen was introduced the patient complained of pain in the right shoulder, slight nausea and pins and needles sensation in his fingers. The treatment was discontinued entirely for several days and then instituted again. No ill effects seemed to result, although studies of his blood and urine were not made. The dosage of diphenylhydantoin sodium and trimethadione was reduced about March 1, 1948. He received 2 capsules containing 1½ grains (98 mg.) of diphenylhydantoin sodium and 2 trimethadione tablets (195 mg. each) one day and one-half that dose on the alternate day. On May 1 the patient went for a hike in the woods, and that evening he noticed puffiness of his face. On May 9 he began to have pain in his shoulders and nausea but no vomiting. During the following week he noticed a gradual increase in the size of his thighs and legs. The patient denies any recent infection of the respiratory tract, sore throat, chilling or other illness or having taken any medicines other than those listed.

On May 15 the patient came for examination because of his obvious massive body swelling. He weighed 173 pounds (79 Kg.), fully dressed, although he claimed his usual weight was 148 pounds (67 Kg.). The boy was well developed and rather pale, with puffy eyes. He had a residual weakness of the right side of his face. His pupils were equal and responded to light and in accommodation, and the retinal vessels appeared normal. His tonsils were absent, the tongue was furrowed but not abnormal in color. His pulse rate at rest was 64 and entirely regular. Blood pressure was 132 systolic and 84 diastolic. There was no evidence of basal congestion in his lungs and no scrotal edema. Examination of the abdomen did not reveal enlarged organs or areas of tenderness, but the abdominal wall felt thickened. There was decided thickening with pitting edema of his thighs and feet. His urine had a specific gravity of 1.035 and a thick cloud of albumin when boiled with acetic acid. Microscopic examination showed abundant mucus, about 1 white blood cell per low power field and a few hyaline and granular casts. His red cell count was 5,300,000 and hemoglobin 105 per cent, or 16.3 Gm. per hundred cubic centimeters. The white blood cell count was 12,800, with a differential count of 56 per cent polymorphonuclear leukocytes, 40 per cent lymphocytes and 4 per cent eosinophils. His nonprotein nitrogen was 32 mg. per hundred cubic centimeters. The blood cholesterol was 266 mg., serum albumin 2.8 Gm., globulin 1.6 Gm. and total protein 4.4 Gm. per hundred cubic centimeters. The reaction to the Kline test was negative.

All medication was withdrawn. The patient was confined to bed, with a salt-poor diet and fluid intake of 1,800 cc. per day. The following day his pulse rate was 48, but otherwise there was no change. On May 18 he had a temperature of 101 F. by mouth, nausea, mild general abdominal discomfort and extensive painful indurated erythema of the skin of both thighs. He was then admitted to the New Britain General Hospital. On admission his weight, without clothing, was 171 pounds (78 Kg.). The same diet was continued and similar fluid intake, and he was given intramuscular doses of 300,000 units of penicillin ("duracillin") daily for ten days. He became afebrile the day after admission and remained so throughout his twelve days in the hospital. The erythema disappeared in forty-eight hours and all symptoms of discomfort cleared up. A detailed record of his intake of fluids and output of urine is included in the chart.

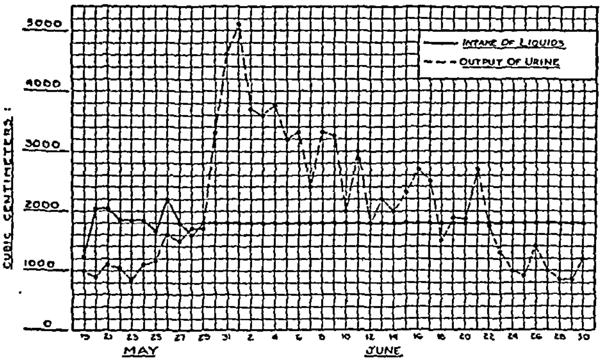
During the first week that the patient was in the hospital results of daily urinalyses showed little change from those reported on May 15. The specific gravity of the urine remained

---

From the Medical Service, New Britain General Hospital, New Britain, Conn.

[1] Barnett, H. L.; Simons, D. J., and Wells, R. E., Jr.: Nephrotic Syndrome Occurring During Tridione Therapy, Am. J. Med. 4: 760 (May) 1948.

at or about 1.025. The quantitative test showed 15 Gm. of albumin per thousand cubic centimeters of urine. On May 27 the urine had large numbers of hyaline casts with a few granular and waxy casts and 10 to 15 pus cells per high power field. His quantitative albumin that day was 21 Gm. per liter. Red blood cells were rare or absent from all of the urine specimens. Phenolsulfonphthalein was given intravenously, and 15 per cent was obtained in the urine voided ten minutes later and 40 per cent obtained seventy minutes after administration of the dye. Blood cholesterol on May 24 was 167 mg. and plasma chlorides were 570 mg. On May 29 the serum albumin was 3.1, globulin 1.3 and total protein 4.4 Gm. On May 30, when the patient was discharged to his home, he was asymptomatic, but the appearance of the edema had not changed and he had lost only 3 pounds (1.3 Kg.). It may be noted from the chart that the output of urine per day had been approximately 1,200 cc. On May 30 the output rose abruptly to 3,320 cc.; on June 1 it reached the maximum of 5,130 cc., and on that date his undressed weight was 154 pounds (70 Kg.). On June 10 the serum albumin was 1.8 Gm., globulin 1.7 Gm. and total protein 3.5 Gm. On that day he weighed 141 pounds (64 Kg.), the lowest weight recorded, after which his weight slowly increased. The urinary output continued to exceed intake until June 19. On June 21 the serum albumin was 4.8 and globulin 0.6 Gm., total protein 5.4 Gm. Soon after the patient's diuresis had been fully established he was allowed to take salt according to taste and to choose foods without restriction.



Daily record of liquid intake and urine output (in cubic centimeters).

On June 21, seizures similar to those he had had a year previously recurred. Each seizure was estimated to last from 30 to 60 seconds. The patient stated that he felt cut off from his surroundings and felt as if he were "walking on a pillow." Three seizures occurred on June 21 and six on June 22. From June 23 on he took ½ grain (33 mg.) of "mebaral" (N-methylethylphenylmalonylurea) three times a day. On August 19 the patient reported that no seizures had recurred. Urinalyses on several occasions after July 15 were made and showed no evidence of albumin or of cells or casts. He claimed that he felt as well as he had ever felt.

### COMMENT

Nephrosis developed ten months after the beginning of treatment with trimethadione, and the patient recovered without residual symptoms three weeks after withdrawal of the medicine. The experience of this patient adds weight to the conclusions made by Barnett, Simons and Wells [1] that trimethadione apparently caused nephrosis in their patient. A rather long list of toxic reactions to this drug has been presented by Lennox [2] without mention of its effect on the body in producing the nephrotic syndrome. The usefulness of the medicine in the treatment of petit mal has been recently stressed by Gibbs.[3] No record has been found other than the report of Barnett and his co-workers of nephrosis occurring during trimethadione therapy. Fortunately in their experience, and in mine, the prognosis has been good, with complete disappearance of all evidence of renal disease. The nephrosis induced by trimethadione seems unlike that from the common chemical nephrotoxic agents and resembles the so-called lipid nephrosis except for the brief duration of trimethadione nephrosis. The mode of action of trimethadione seems to be to provoke an increased porosity of the glomerulus to proteins. In this case the patient proved to be susceptible to infection during his illness in a manner that is common in nephrosis. He showed spontaneous diuresis, and, while the evidence is incomplete, the diuresis seems to have been independent of any substantial rise in the level of blood protein. Some additional light may be thrown on the mechanism of nephrosis by means of additional studies on this unique disorder.

---

## Council on Pharmacy and Chemistry

### REPORTS OF THE COUNCIL

*The Council has authorized publication of the following statements.*
Austin Smith, M.D., *Secretary.*

### ANNUAL MEETING OF THE COUNCIL ON PHARMACY AND CHEMISTRY

The Council on Pharmacy and Chemistry held its annual meeting on Nov. 12, 1948 at the headquarters of the American Medical Association in Chicago. Dr. Torald Sollmann and Dr. James P. Leake were reelected Chairman and Vice-Chairman of the Council.

Following is a brief résumé of some of the topics from the Council agenda and of the actions taken by the Council:

*ACS Serum.*—The status of this substance, including its preparation, availability and claimed usefulness, was reviewed, but it was agreed that no action seemed indicated at this time.

*"Over-the-Counter" Sale of Large Doses of Penicillin for the Prevention of Gonorrheal Infections.*—The information contained in a report by Dr. Harry Eagle and others was reviewed, as was information obtained from other sources. Consideration was also given to the general problem of the release of penicillin for "over-the-counter" sale, regardless of its intended use. It was agreed by the Council that the difficulty of controlling such sale and the use of a product such as penicillin cannot be stressed too strongly and that the safety of the general population must be considered at all times. In addition, the Council agreed that the work reported by Dr. Eagle and associates represents an interesting approach to a general health problem but that further investigation seems in order before the Council can issue a statement.

*Status of Sulfonamide Compounds.*—The status of the sulfonamide compounds was reviewed by the Council, and it was agreed that sulfanilamide and sulfaguanidine should be deleted from the next edition of New and Nonofficial Remedies. Apparently very little of these substances is now used in the therapy of human infections in the United States.

*Status of Newer Antibiotics.*—Polymyxin, "chloromycetin" and aureomycin, three antibiotics available for some time for experimental use, were discussed with a view to determining the possible role that these materials will have in chemotherapy. At least one of them, aureomycin, is commercially available. Polymyxin seems to have the property of producing temporary renal tubular dysfunction. In addition, it is a difficult antibiotic to extract and it seems unlikely that it will be on the market in the near future. It apparently is a mixture of four or five polypeptides, each of which has some antibacterial effect on certain gram-negative organisms. "Chloromycetin" is effective against rickettsial infections and certain experimental infections produced by gram-negative bacteria. It offers promise of having specific effectiveness in the treatment of typhoid. Aureomycin has been used in the treatment of spotted fever, murine typhus, Q-fever, Brill's disease, staphylococcic infections, certain bacillary urinary infections, group D hemolytic streptococci and streptococcus faecalis infections, acute undulant fever, primary atypical pneumonia and lymphoagranuloma inguinale. The Council's consideration of these antibiotics represented merely a review of their status, and no recommendations were forthcoming.

*Ultraviolet Irradiation of Plasma and Serum.*—The Council has accepted for inclusion in New and Nonofficial Remedies a rabies vaccine that has been subjected to ultraviolet irradiation. However, it has held in abeyance submitted brands of irradiated plasma. On the basis of data presented at the annual meeting it was agreed that the evidence seems to indicate that ultraviolet irradiation will kill the virus responsible for serum jaundice and that plasma and serum submitted to such irradiation can be included in New and Nonofficial Remedies, provided the other requirements of the Council are met.

[2] Lennox, W. G.: Tridione in the Treatment of Epilepsy, J. A. M. A. **134**: 138 (May 10) 1947.

[3] Gibbs, F. A.: New Drugs of Value in the Treatment of Epilepsy, Ann. Int. Med. **27**: 548 (Oct.) 1947.

*Antihistaminic Preparations.*—The status of antihistaminic preparations was reviewed and it seemed apparent that the number of preparations on the market has served to provide confusion, and before others are introduced they should show certain advantages. The Council then agreed that it would be wise to consider criteria or qualifications for acceptance of any new antihistaminic preparations and suggested for consideration criteria such as the following: (1) that the drug have a greatly increased potency over those now available so that it would be possible to give relief to certain allergic manifestations not relievable now; (2) that the drug be much less toxic than any now available, not in terms of 10 per cent less toxicity but many times this figure; (3) that the drug be more active for a much greater duration, not just for three or four hours but several times this, possibly up to twenty-four hours; (4) that the drug have other than histaminic action, such as sympathomimetic action, or some other action that in some way interferes with the allergic mechanism. These criteria are not intended to serve as means of limiting Council acceptance but as objectives for researchers and manufacturers when they explore this field.

*Estrogenic Preparations.*—One of the problems that face the Council and the medical profession is concerned with the duplication of preparations. The Council authorized the preparation of a report pointing out the undesirable features of unnecessary duplication, citing the antihistaminic drugs and estrogenic preparations as illustrations. This report appears elsewhere in the Council column and is entitled "Too Many Drugs."

*Status of Chlorguanide Hydrochloride Dosages.*—Recent developments indicate a need for a change in the dosage schedules for this preparation. For example, it now seems evident that 0.3 Gm. of chlorguanide hydrochloride is often essential for the suppression of malaria and for the prevention or suppression of vivax malaria. Manufacturers who have submitted brands of this preparation to the Council will be asked to take this into consideration when their literature is revised.

*Typhoid and Paratyphoid Vaccine Combined.*—At its last meeting (Nov. 14-15, 1947) the Council voted to omit typhoid and paratyphoid vaccines combined from New and Nonofficial Remedies. Since that time some correspondence has ensued so that the Council gave reconsideration to the status of such mixtures. It concluded, however, that there was not sufficient evidence to justify a change in the Council's stand. Nevertheless, the Council authorized the preparation of an article for publication. It is anticipated that one will be forthcoming in the near future.

*Emulsified Mineral Oil.*—It appears possible that highly emulsified mineral oil may achieve a more intimate relation with the intestinal tract tissues than the unmodified mineral oil. However, further evidence, especially in human beings, is needed to explore fully this possibility and, until such evidence is forthcoming, the Council will continue with its acceptance of mineral oil preparations that are manufactured by normal pharmaceutical practice.

*Reacceptance of Products.*—The Council gave consideration to a technic whereby reacceptance procedures can be expedited.

*Committee on Toxicology.*—For some time the Council has been interested in toxicologic problems and has had an exploratory committee to prepare recommendations for meeting some of the problems inherent in this field. The Council voted to continue the existence of such a committee and of a subcommittee on pesticides to explore the whole problem and to determine the Council's ultimate consideration of pesticides and related substances.

*Controls in the Manufacture of Drug Products.*—The Council gave consideration to problems related to the control of the manufacture of drug products and to the standards set forth in the official compendia. No formal action was taken by the Council.

*Scope of New and Nonofficial Remedies.*—The scope of N. N. R. was considered and attention given to expediting consideration of items coming within the purview of the Council.

*Coined Names.*—The status of trademarked names and of generic names in relation to Council acceptance was reviewed. The Council reaffirmed the action previously taken for the consideration of names concerning which there may be a difference of opinion. This action provides a means whereby the Council may obtain comments from the officers of the American Medical Association Sections when there is a question of what constitutes a misleading or therapeutically suggestive name.

*Inert Glandular Preparations.*—The Council gave consideration to the marketing of inert glandular preparations and their exclusion from the market by legal procedures. No formal action was taken.

*Excessive Charges for Drugs.*—The Council gave consideration to the claims that excessive charges for drugs may exist in some quarters and voted that an article on this subject be prepared. This article appears elsewhere in the Council column under the title "Exorbitant Charges for Drugs."

*International Nomenclature.*—The advantage of using the same names for chemical substances and drugs throughout the world was discussed by the Council and it was agreed that the Council would cooperate in any way that it could to encourage such recognition of uniform nomenclature.

## TOO MANY DRUGS?

A fundamental requirement to successful treatment is that the physician have the clearest possible understanding of the remedial agents that he prescribes. This is difficult at best, and is rendered increasingly difficult with multiplication of agents that are nearly but not quite equivalent. Each may show minor differences, which may or may not be practically important, but which are difficult to learn if he spreads his experience too widely and therefore too thinly, as he is urged to do when pharmaceutical firms introduce and promote many actual or near duplicates, with the chief purpose of profiting in a presumably lucrative field, rather than with any real consideration for the welfare of the public or of the interest of medical science and practice. A satisfactory advance has been achieved in the elimination of superfluous drugs from the Pharmacopeia, and the National Formulary has made praiseworthy strides in this direction, but the catalogs of drug houses continue to be overcrowded. The processes of natural selection and the operation of economics tend toward the final survival of the fittest and the eventual elimination of the less fit, but they operate slowly. In the meantime, as new fields open, there is the gold rush to stake out claims and make a killing while the going is still good. But it is particularly in these new and relatively unexplored fields where the harm of unnecessary duplication is greatest, where it interferes most seriously with the acquisition of the precise information that is essential to the proper evaluation of the scope and of the dangers of new medications. Two examples that come to mind are the estrogenic preparations and the "anti-histaminic" drugs. In both cases, synthetic chemistry is able to produce practically numberless agents. Both fields are already crowded and overcrowded, but new agents are still being introduced at an alarming rate which makes it practically impossible to acquire the experience that is necessary to determine what advantages, if any, they possess over the older similar agents. There is another side to the argument, however, for few if any therapeutic agents are ideal. Improvements, increased efficiency, fewer side actions and lower toxicity should be sought for. Skilful experimentation in this direction should be encouraged, not obstructed, but this thorough experimentation should *precede* the introduction into medical practice. It were better, much better, for medical practice and probably for financial dividends, if modifications which do not offer substantial advantages were shunted into the discard before they see publicity and add to the confusion of practitioners. As an example, it has been suggested to the Council that it decline to accept further antihistaminic drugs unless they offer at least one of the following advantages over the agents already accepted: (1) that the drug have a greatly increased potency over those now available so that it would be possible to give relief to certain allergic manifestations not relievable now; (2) that the drug be much less toxic than any now available and not 10 or 20 per cent less toxic; (3) that the drug be more active for a much greater duration, not just three or four hours, but for twenty-four hours; (4) that the drug have other than histaminic actions, such as sympathomimetic action, or some other action that in some way interferes with the allergic mechanism.

The Council agrees fully that some such criteria should be applied to all fields that are becoming overcrowded, but the Council believes that it would be much better if this is done by voluntary action of the individual manufacturers, rather than by the fiat of any central agency. The latter could easily tend to stifle legitimate and useful competition by cooperative manufacturers, while the less conscientious would go ahead and modify or pirate without Council acceptance. The Council therefore refers the problem to the good sense of the manufacturers who value the respect and good will of the medical profession.

## EXORBITANT CHARGES FOR DRUGS

One of the tritest jokes of the "gay nineties" was the high profit of the druggist: Why, he would charge as much as twenty-five cents for a prescription for an eyewater which cost him perhaps a fraction of a cent! It was always good for a laugh, generally good natured, for the sum total did not bankrupt the purchaser, and the public knew that their good neighbor the druggist was not waxing rich from the sale of prescriptions, but was happy if he made a modest living. The public, however, did not realize that the price of the prescription was not merely for the ingredients, but also for the time, skill and responsibility of the compounder, and a certain amount of "standby" pay. They would not expect a lawyer's fee to be based solely on the amount of paper that he used, but with the druggist it was different. Perhaps pharmacists were somewhat to blame, as they did not sufficiently emphasize the ingredient of professional service; but one does not get very far in attempting a serious argument on a good-natured joke. With the rising cost of living, the invisible service charge, too, has risen, but for most of the older drugs the total is still within reason, and the public is generally willing to pay the price, as it realizes, at least subconsciously, that the laborer is worthy of his hire, even though he is a member of a profession, and, after all, a dollar or two can generally be afforded without breaking the bank. Of late, however, a new item has entered into the scene, the high cost of some of the newer drugs, especially the antibiotics. The manufacturer has generally incurred heavy expenses in developing and manufacturing these drugs, and he must pass on these costs to the pharmacist or hospital, or go out of business. The pharmacist in turn must pass it on to the consumer, and the hospital must in some way find the funds for those who are unable to pay in full. These costs may now reach very substantial amounts and be a serious hardship. This is, indeed, unfortunate, but so it is, and one cannot reasonably object to a reasonable price including a reasonable service charge; but the fact that the reasonable charges may be necessarily so high as to be a serious burden when added to the other costs of sickness makes it imperative that the price be kept as low as possible. The Council has been informed, however, that this is not always the case; that some pharmacists have made this a pretext for raising the price of less expensive drugs, pretending that these were also "expensive," and that some hospitals have been known to make exorbitant charges for drugs to patients able to pay, as a hidden means of financing the deficits with which most hospitals are all too familiar, and, it must be regretfully, admitted, some physicians are guilty of this practice. The Council would urge those who are guilty of such practices, perhaps thoughtlessly, to ask themselves these two questions:

Are not exorbitant profits a hold-up of the unfortunate and generally helpless victim? Is it not a fraud to suggest that high prices are due to the cost of the drug when this is not wholely true?

Those who are not guilty of such extortion may well consider that the bad practices of a few are apt to be blamed on all.

## NEW AND NONOFFICIAL REMEDIES

*The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.*

AUSTIN SMITH, M.D., *Secretary.*

**CONTRACEPTIVE JELLIES AND CREAMS** (See New and Nonofficial Remedies 1947, p. 271).

The following additional dosage forms have been accepted:

HOLLAND-RANTOS CO., INC., NEW YORK

**Koromex Cream:** 135 Gm. (refill tube).

**Koromex Jelly:** 142 Gm. (refill tube).

U. S. Trademark 213,756.

**METHADONE HYDROCHLORIDE** (See THE JOURNAL, Aug. 14, 1948, p. 1382).

*The following dosage form has been accepted:*

S. E. MASSENGILL CO., BRISTOL, TENN.

**Solution Methadone Hydrochloride:** 10 mg. per cc., 1 cc. ampuls.

**Tablets Methadone Hydrochloride:** 2.5 mg., 5 mg. and 7.5 mg.

# Council on Physical Medicine

## REPORTS OF THE COUNCIL

*The Council on Physical Medicine has authorized publication of the following reports.* HOWARD A. CARTER, *Secretary.*

## MICROTONE AUDIOMATIC, MODEL T-5, HEARING AID ACCEPTABLE

Manufacturer: The Microtone Company, 4602 Nicollet Avenue, Minneapolis 9.

The Microtone Audiomatic, Model T-5, Hearing Aid is a battery-contained type of hearing aid. A rectangular case of white plastic material contains microphone, amplifier and batteries.

Microtone Audiomatic T-5 Hearing Aid.

The outside dimensions of the case, excluding clip, are 123 by 61 by 25 mm. (4¾ by 2½ by 1 inch). The weight, including batteries, is just under 230 Gm. (9 ounces). The A battery and the 30 volt B battery are both of the zinc-carbon type. The A battery drain is 60 milliamperes and the B battery drain is approximately 0.55 milliampere.

The Council verified the manufacturer's claims regarding the frequency characteristics of the instrument as performed in the firm's laboratory. The following are results of a performance test on 2 subjects who were habitual users of hearing aids:

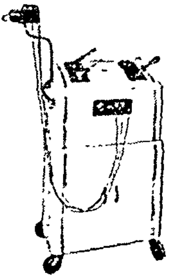
| Subject | Acoustic Gain Greater than | Articulation Scores<br>Model T-5 | <br>Reference |
|---|---|---|---|
| A | 44 db. | 86% | 80% |
| B | 50 db. | 87% | 77% |

The Council on Physical Medicine voted to include the Microtone Audiomatic, Model T-5, Hearing Aid in its list of accepted devices.

## LIEBEL-FLARSHEIM MODEL AG BOVIE ELECTROSURGICAL UNIT ACCEPTABLE

Manufacturer: The Liebel-Flarsheim Company, 303 West Third Street, Cincinnati 2.

The Liebel-Flarsheim Model "AG" Bovie Electrosurgical Unit is designed to succeed the Improved Davis-Bovie Electrosurgical Unit manufactured by the same firm and on the accepted list. According to the manufacturer, the new unit retains all the essential principles of its predecessor models and in addition incorporates a tube-cutting current and the use of automatic instead of manual adjustment of the spark gaps. The term "tube-cutting" means tissue severance by the use of high frequency oscillations produced by vacuum tubes. This current is used when it is desirable to have no hemostatic effect with the cut. When hemostatic effect is necessary, the spark-gap cutting currents are used.



Liebel-Flarsheim Model AG Bovie Electrosurgical Unit.

The Council obtained evidence of satisfactory performance by this apparatus in more than 100 surgical cases. The operative procedures represented a fairly wide field of general and abdominal surgery and included some underwater cutting. It was used for coagulation, desiccation and electrocision.

The Council on Physical Medicine voted to include the Liebel Flarsheim AG Bovie Electrosurgical Unit in its list of accepted devices.

## HODGKIN'S DISEASE

An increased number of cases of Hodgkin's disease has apparently been reported during the last twenty years.[1] The increase is considered by some investigators to be due to a wider use of biopsies as a diagnostic measure. However, the Metropolitan Life Insurance Company figures which compare statistics for 1921 and 1936 appear to support the opinion that the disease is increasing, while the statistics of the New York City Department of Health appear to deny it. The incidence of Hodgkin's disease in the United States was recently reported[2] to vary from 0.5 to 2.5 per 100,000 population.

Malpighi wrote the first description of Hodgkin's disease in 1661. Thomas Hodgkin recognized the syndrome as a clinical entity in 1832 and described 7 cases with lymph node and splenic enlargement, cachexia and a fatal termination. Langhans noted giant cells in the lesions in 1872. In 1892, Goldman pointed out that eosinophils were frequently found in the lesions. Dorothy Reed's contribution[3] to the histopathology of Hodgkin's disease appeared in 1902. The histopathologic description is now unequivocal in the majority of cases, but the controversy concerning the origin, nature and etiology continues.

Of many names that have been applied to Hodgkin's disease, the following persist: lymphadenoma, malignant lymphoma, lymphogranuloma, lymphogranulomatosis, malignant granuloma and adenia. Males are affected almost twice as often as females. Any organ containing collections of lymphoid tissue is susceptible to attack. The lymph nodes of the neck are involved first in a majority of cases. They are frequently enlarged in chains, with the nodes varying in size from 2 to 12 cm. However, the lungs and the skin may be the primary site; indeed, almost every organ in the body has been reported to contain typical lesions.

The earliest change detectable in the lymphoid tissue is a proliferation of reticulum cells, increased numbers of mitoses and dilatation of blood vessels and lymph sinuses. As the process develops, the proliferating reticulum cells and lymphocytes fill the lymph and reticular spaces, obliterating any distinction between follicles and sinuses. During this proliferative period, giant cells, plasma cells and eosinophils may appear in large numbers. The established lesions form a mass of lymphocytes, endothelial cells, Langhan's giant cells, Sternberg-Reed cells, lymphoblasts, myelocytes and megakaryocytes. Skin lesions may present special characteristics. Bersack reported a case with terminal miliary spread to the skin in which a biopsy showed a normal epidermis with minimal reaction about the small blood vessels. The early changes observed consisted of slight endothelial and fibroblastic proliferation with a moderate number of lymphocytes throughout the corium. Biopsy later revealed Hodgkin's disease. Rae described a case with pruritus in which the connective tissue of the skin was infiltrated by lymphocytes. Another significant observation is a depletion of lymphoid elements in the spleen and, to some extent, in other organs not involved by a specific lesion. Bersack, who studied the lymph nodes in 225 cases, concluded that in the majority of cases there is sufficient uniformity in the several sections of one lymph node or in simultaneous biopsies from different sites to warrant the characterization of each case on the basis of histology.

The presenting symptom in about 79 per cent of the cases is painless progressive enlargement of a lymph node or nodes; other symptoms are loss of weight and appetite, weakness, fever, pruritus, cough and dyspnea. A majority of cases progress through three stages: (1) a latent period during which the nodes enlarge without symptoms; (2) a period of progression and generalization during which symptoms of varying severity appear, and (3) a period of cachexia which precedes death. One of the distinguishing qualities of Hodgkin's disease is the changing course of events week by week, month by month. No patient experiences all the symptoms noted, and spontaneous remissions and exacerbations occur in the early stages. Fever may begin and end without obvious relation to the enlarged glands, which may increase in size during the fever episode. Not infrequently in patients without fever, pain is a frequent complaint and back pain a common symptom. The most frequent neurologic symptom complex is paraplegia.

A complete history, physical examination, blood and roentgenologic studies and observation of the clinical course help in making a presumptive diagnosis. The differential diagnostic problem involves giant follicular lymphoblastoma, myeloid and lymphatic leukemia, Cohnheim's subleukemic lymphatic leukemia, myeloblastic sarcoma, lymphosarcoma, reticulum cell sarcoma, metastatic carcinoma, Boeck's sarcoid, nonspecific inflammatory adenopathy, certain fungous diseases, lymphogranuloma inguinale, typhoid, brucellosis, tuberculosis, syphilis and infectious mononucleosis. The final criterion rests with the histopathologic appearance of diseased tissue.

[3] Reed, D. M.: On the Pathological Changes in Hodgkin's Disease with Special Reference to Its Relation to Tuberculosis, Johns Hopkins Hosp. Rep. **10:** 133-196, 1902.

Patients have been known to remain in fairly good health for twelve to fourteen years, while others die within ten weeks. Some factors said to be associated with a good prognosis are a normal number of erythrocytes, a nearly normal sedimentation rate, localization of the disease in one area, definite enlargement of external nodes before treatment, gain in weight and absence of leukocytosis or leukopenia. Females have a better prognosis than males. Associated with a poor prognosis are splenomegaly, initial elevation of temperature, considerable pruritus, pulmonary involvement, predominant localization in the abdominal cavity, gastrointestinal symptoms, a steady fall in the number of red cells, decided lymphopenia, pronounced weight loss and a rapid sedimentation rate early in the disease. About 50 per cent of the patients die in the toxic state attending multiple visceral invasion or terminal disease associated with secondary infection. Many patients die with bone marrow exhaustion and aplasia. The secondary effects of roentgen therapy are said to have accounted for some deaths, but improvement in radiotherapeutic technics and more careful laboratory studies have reduced the mortality from this source.

Satisfactory treatment for Hodgkin's disease has not been found. For localized lesions, roentgen irradiation is the treatment of choice. For patients with disseminated lesions, the use of nitrogen mustard therapy with roentgen irradiation of selected specific areas appears to be the most effective method. The problem varies with each patient. Radiologists differ in their criteria of satisfactory therapy. While the palliative effectiveness of persistent, early and thorough roentgen therapy has been repeatedly demonstrated, it must be used with great care in the face of renal insufficiency, active tuberculosis in regions where roentgen therapy is to be applied, acute forms of Hodgkin's disease, toxic depression of the bone marrow and deleterious effects of previous irradiation. Radioactive phosphorus given intravenously has produced disappointing results. Surgical intervention may be necessary to relieve pressure symptoms. Prompt removal of the spinal cord block in paraplegia may be indicated in order to prevent permanent damage. Surgery in Hodgkin's disease involving accessible nodes is said to give better results than are usually expected. The list of chemotherapeutic agents which have been tried is long. Results with the sulfonamide compounds have been essentially negative, as have been repeated attempts by means of vaccines and other biologicals. Nitrogen mustards appear to act similarly to roentgen therapy and may be of great value when roentgen therapy is no longer effective.

The theories advanced concerning the nature of Hodgkin's disease include: It is (1) a neoplasm; (2) an inflammation; (3) a metabolic abnormality; (4) it is midway between an inflammation and a neoplasm. None of them has been proved. The disease has never been produced experimentally in animals. Neither Feldman, who has studied hundreds of neoplasms from animals, nor Fox, who has observed thousands of captive wild animals, has seen in them a case resembling Hodgkin's disease.

## ARTERIAL HYPERTENSION IN THE CHICKEN

Selye,[1] while investigating the pharmacology of corticoid hormones, discovered that overdosage with desoxycorticosterone acetate in the chick elicits nephrosclerosis, cardiovascular changes, water retention and diarrhea, symptoms similar to those of avian Bright's disease. This action of the corticoid hormone was especially readily obtained in birds given 0.3 per cent sodium chloride instead of drinking water. Selye also demonstrated that salt alone sufficed to produce in chicks a syndrome characterized by nephrosclerosis and disturbances of water metabolism. Krakower and Heino[2] found that in chicks on high salt intake there was elevation of blood pressure, a definite renal glomerular enlargement, new formation of glomerular tufts and increased tortuosity and medial hypertrophy of renal arteries and preglomerular arterioles.

Katz and his co-workers[3] report experiments in which chicks were placed on a diet of mash and tap water for sixteen days. Three control blood pressures on each chicken were taken during this period with the Hamilton manometer by means of a small needle inserted into the sciatic artery. The drinking water was then replaced by a 0.9 per cent sodium chloride solution. After thirty-three days when the rise in pressure was seen to be moderate, the sodium chloride concentration was increased to 1.2 per cent. The salt solution was replaced twenty-six days later by tap water for thirteen days. A second period of administration of 1.2 per cent salt solution was then instituted for twenty-two days. After a final period of ten days on tap water, the chickens were killed. The control blood pressures at the beginning of the experiment averaged 132 mm. of mercury systolic and 117 diastolic. The high level of the normal diastolic pressure in the chicken appears to be related to its high normal body temperature of 42 C.

---

[2] Krakower, C. A., and Heino, H. E.: Relationship of Growth and Nutrition to Cardiorenal Changes Induced in Birds by a High Salt Intake, Arch. Path. **44** :143-162 (Aug.) 1947.

[3] Lenel, R.; Katz, L. N., and Rodbard, S.: Arterial Hypertension in the Chicken, Am. J. Physiol. **152**: 557-562 (March) 1948.

The blood pressure did not rise significantly at the beginning of the administration of 0.9 per cent sodium chloride. At the end of seventeen days it had risen 22 mm. of mercury systolic and 17 diastolic. It then remained unchanged until the salt concentration was increased to 1.2 per cent. This produced a further increase of 25 mm. systolic and 9 mm. diastolic, with the average pressure reaching 183 mm. of mercury systolic and 154 diastolic. The total rise over the control values was 51 mm. of mercury systolic and 37 diastolic. When the salt was discontinued a prompt fall in pressure occurred, averaging 43 mm. of mercury systolic and 28 diastolic and bringing the pressure nearly to the control levels. With the readministration of salt in the drinking water, a rise in pressure was again observed, with a fall after the birds were again returned to ordinary tap water.

These authors regarded as significant the increase in both systolic and diastolic blood pressures in the birds during the course of high salt intake because the upward trend was present in all of the birds. Blood pressures in a control series of 5 normal young chickens taken over a period of eighty days was found to be remarkably constant. Also striking was the effect of the return to tap water, which produced an average drop of 43 mm. of mercury systolic and 28 mm. diastolic. The authors feel justified in assuming a direct relationship between high salt intake and the rise in blood pressure in the chicken. The mechanism of this phenomenon is not clear. An increased blood volume is probably not involved as their direct measurements showed, and as the pronounced loss of weight and dehydration would seem to indicate. Necropsies on these birds showed some hyperplasia and proliferation of glomerular tufts and Bowman's capsule with some compression of the capillaries.

The production of hypertension in the chicken by a high salt intake in the drinking water, the authors believe, is pertinent to the general problem of the genesis of hypertension. Thus, desoxycorticosterone, which affects the excretion of sodium and potassium, also produces changes in the blood pressure in men and animals. The low blood pressures seen in patients with addisonian disease are also associated with a low plasma sodium concentration, and this hypotension can be treated by the oral administration of sodium chloride. The recent emphasis on the use of salt-free diets in the treatment of arterial hypertension, which originated primarily on an empiric basis, may be considered to have some support from these and other findings.

## Current Comment

### FLUORINE VERSUS DENTAL CARIES

Attempts to determine the value of fluorine in the prevention of dental caries in rats are reported by Cheyne[1] of the College of Dentistry, University of Iowa. Since McClure[2] and others have presented data which show that significant reduction in the incidence of induced dental caries in rats is not demonstrable as a result of postnatal applications of fluorine, Cheyne limited his study to the effects of prenatal fluorinization. Eighteen young rats were obtained from mothers which had received daily administrations of potassium fluoride during pregnancy. As controls, 27 young were selected from mothers which had not received fluorine. Half of the fluorinized (mottled teeth) young and 12 of the 27 nonfluorinized young were subjected to total extirpations of the salivary glands[3] at the age of 24 days. On the forty-second day all animals were placed on a caries-producing diet,[4] without restriction on amounts of food and distilled water. After one hundred and four days on this diet, the animals were chloroformed and all molar teeth were examined under a binocular microscope. Doubtful teeth were decalcified and examined histologically. The number of fractured cusps, carious cuspal involvements and carious teeth was determined for each animal. Among the control nonfluorinized rats with intact salivary glands there was an average of 1.8 carious teeth per animal. In a parallel test with the fluorinized rats, there was an average of 1.5 carious teeth. Similar differences were noted in the two desalivated groups. The two nonfluorinized groups showed an average of 6.2 carious teeth per animal, while the average was 5 carious teeth in the two fluorinized groups. A more striking effect was seen in a study of the effect of desalivation. The two desalivated groups showed an average of 9.5 carious teeth per animal, while in the two control groups with normal salivary glands, the average was 1.7 carious teeth. No theory is as yet suggested to account for this apparent prophylactic effect of normal saliva.

# ORGANIZATION SECTION

## Official Notes

### DR. BAUER TO ADVISE WITH AMERICAN MILITARY GOVERNMENT

Dr. W. W. Bauer, director, Bureau of Health Education, American Medical Association, will leave from New York March 3 for a three months' assignment in Germany. He has been designated visiting expert in the employ of the Army to advise with the American Military Government on problems of public health, health education and medical organization.

### "STANDARD NOMENCLATURE OF DISEASE AND THE STANDARD NOMENCLATURE OF OPERATIONS"

#### Meeting of the Editorial Advisory Board Held on Dec. 4, 1948, in the American Medical Association Building

Dr. George Baehr, Chairman

The agenda consisted of several suggested changes for the 1950 revision of the "Standard Nomenclature." After each suggestion was submitted to the Board for their approval, a discussion period followed in which the members stated their views.

1. Title (suggested changes):
    (*a*) To be left as is with the exception that the word "disease" should be changed to "diseases" to conform with "operations."
    (*b*) To be combined as "Standard Nomenclature of Diseases and Operations."
    (*c*) As other sections may be added, the combined title "Standard Nomenclature of Medicine" is suggested.

It was the unanimous opinion of the Board that the title for the fourth edition be "Standard Nomenclature of Diseases and Operations."

2. Inclusion of code numbers of "International Statistical Classification of Diseases, Injuries and Causes of Death." Place of inclusion:
    (*a*) The index is not suitable as it now stands because it is a general group index rather than a single disease index.
    (*b*) The body of the book appears to be a preferable place for insertions of these numbers because diagnoses are there broken down into more specific entities.

Dr. George Baehr, New York: Numbers of the International List should be included in the body of the book in italics and in parentheses. An addendum should be placed in back of the book. For example, rheumatic fever would be listed and then after it would be listed all the numbers in the text that referred to this disease. This method would greatly simplify the statistician's work.

Dr. E. T. Thompson, Chicago: This system would provide one standard translation so that each department would not have to make its own code. The record librarian could send her report in to the county health department in International numbers. This would make it much easier for the state health department when they received the report because it would save them the work of translating the diagnoses into International numbers for statistical purposes. The suggestion was made that the International List could be printed as a supplement to the "Standard Nomenclature" and sold separately.

Dr. Baehr: It is probable that if they are not published together, people will use the "International Classification" alone. It is the consensus that it would be wise to include the "International Statistical List of Diseases, Injuries and Causes of Death" and have it in the body of the text, as was done in the first edition, to the right of each term in parentheses and in clear italics. Then in the back of the book the International List numbers and diagnoses would be published in the form of an addendum. Under each of the International numbers there would be listed all of the code numbers in the "Nomenclature" that refer to it.

Dr. Morris Fishbein, Chicago: Before making a decision, it would be desirable to prepare a sample. For example, take the first heading and take the section in "Nomenclature" that deals with the same thing and make it up just as if it were going to be published in the book; then we will have an idea of how it looks before we actually do it.

Dr. Baehr: I do not think that one can take every entry in the "International List" that is going to be used because it will be too bulky and the book would have to have an index of many terms which were not even used in this country.

Dr. Fishbein: The book is already too big; that is, in the list of entries. A trial of a section should definitely be made and proofs sent out to committee members so that they can make recommendations or changes. The proofs can be made here at the American Medical Association. There is nothing more confusing than to open to an index and find listed after it 22 different numbers that refer you to something else.

Dr. Baehr: We will leave it then until we have a sample, and we have gone on record to include the "International List" in the forthcoming edition of "Standard Nomenclature."

Dr. Fishbein: The preface of the book should explain the difference between "Standard Nomenclature" and the "International List" so that the difference would be clear.

Dr. Thompson: The difficult part of the task is going to be to get the International number behind the Standard number.

Dr. Fishbein: The speed of medical progress is so great that many terms are out of date by the time that the work is published.

3. Inclusion of pathologic diagnoses:
    (*a*) Present overlapping; many diagnoses now listed can be used either as clinical or pathologic diagnoses.
    (*b*) A third number to indicate type of tissue involved in addition to numbers which now indicate topography and etiology has been suggested for use in coding pathologic diagnoses.

*Example: Hodgkin's Disease of Lung*

| Topographic | Etiologic | Tissue |
|---|---|---|
| Lung | Hyperplasia | Pleomorphic Histiocytic |
| 360 | 954 | (Code number to be given) |

As the book now stands diagnosis such as "Hodgkin's disease of lung" cannot be coded.
    (*c*) Additional pathologic diagnoses may be added to the end of each section to allow for both clinical and pathologic coding.

Dr. Richard Plunkett, Chicago: Dr. Perry is particularly interested in having a third number included. Some of the numbers that are now used are really tissue numbers and not topographic numbers.

Dr. James R. Miller, Hartford, Conn.: The idea is to make statistical research easier and not to do the work for the clinicians.

Dr. Plunkett: The book as it now stands codes according to etiology and topography, but some pathologic diagnoses are included.

Dr. Baehr: To do all the work before 1950 and to get the agreement from the pathologists would be impossible.

Dr. Plunkett: Diagnoses are coming in that refer to Hodgkin's disease of various organs. As the book now stands, it is impossible to provide a coding for such a diagnosis because Hodgkin's disease is a general disease and tissue would have to be specified as well as topography.

Dr. Halbert L. Dunn, Washington, D. C.: I suggest that pathologists develop a three column code of their own that would cross against "Standard Nomenclature" number.

Dr. Baehr: The pathologists should try this out before it is considered for this edition. They could have this on trial for a number of years so that their pathologic society could consider it, and then, afterward, if we approve of it, we could include it in "Standard Nomenclature." It is necessary for this committee to have the last word on everything that is done. Specialists tend to want their section of the book developed to the largest extent possible. Committees should not be full of extremists. We should make changes to keep up to date, and we should do it cautiously, and this committee should have the final word on everything. It is, then, the consensus of this Board that the pathologists themselves develop a pathologic classification which they should employ so that we can see how the system works.

Dr. Plunkett: There are many diagnoses in the book that are now both clinical and pathologic.

Dr. Thompson: Many of these problems are purely a matter of indexing.

Mrs. Adaline C. Hayden, Chicago: Pathologists are complaining that the book is not complete enough.

Dr. Baehr: We can get copies of a good list of pathologic diagnoses from the Institute of Pathology and let us examine them to see whether there are any useful parts that we can use. In regard to the adding of pathologic diagnoses to the end of each section to allow for both clinical and pathologic coding, let us defer action until we have time to examine the lists.

4. It is suggested that all supplementary terms be listed in one section rather than following each section.

Mrs. Hayden: Sections on supplementary terms should all be gathered together in one section so that there would be no trouble in finding them. This would simplify the record librarian's work.

Dr. Baehr: This arrangement would probably not be agreeable to the American Heart Association.

Dr. Thompson: Lists of supplementary terms should be indented in the book with a thumb index such as is at present done with the disease and operative indexes.

Dr. Baehr: It would be wise to refer this to the cardiovascular and nervous committees. Letters should be sent to the members of these committees telling them that there are four supplementary lists and that it would be much easier for the record librarian and all others using the book if all four lists were put into one section. Action relative to this matter shall then be deferred until we know how violent their reaction is going to be. Refer the matter to the committees when we set them up, and then bring it back again to this committee.

5. Should a dental committee be set up for the expansion of the dental section?

Dr. Plunkett: Hospitals which have dental departments do not feel that the two page dental section in "Standard Nomenclature" is sufficient.

Dr. Baehr: We should have some suggestions from the Dental Committee with the understanding that we are not writing a Nomenclature solely for dental purposes. It is the unanimous opinion of this Board that a dental committee be set up.

6. Suggestion has been made that eponyms be included in the index rather than as a separate section.

It was the consensus that the eponyms should be included in the general index.

7. Shall procedures be added to the operations' index such as, (Insufflation of uterus with air (Rubin's Test) )?

Dr. Baehr: We should ask for suggestions about procedures from various committees. The consensus was that the desirability of including procedures, therapeutic and diagnostic, to the operations' index should be explored by the committees, particularly by the committee on operations.

8. Decision is required on the retention of the anesthesia section. Most hospitals do not code anesthetics in their record departments.

Dr. Thompson: The section should be retained, and any new anesthetics should be included as a matter of terminology.

Dr. Baehr: The consensus is that the anesthesia section should be retained, improved and brought up to date.

Dr. Miller: Hospitals do not use the anesthesia section often. The section is not being used to advantage.

Dr. Baehr: Defer decision on this matter and refer to Dr. Plunkett for submission to committees for exploration.

9. Appointment of Nomenclature Committees:
   (a) It is suggested that committees of three be selected and approved by the Editorial Advisory Board from the list of suggested committee appointments which was distributed to each member of the Board. The persons listed have served previously or have indicated their willingness to serve in consultant or committee capacity for the 1950 revision. Other persons may be named by the Editorial Advisory Board.
   (b) Committees may be selected and contacted by the Editor and subsequently approved by correspondence with the chairman and other members of the Editorial Advisory Board.

Dr. Baehr: It is important that there be at least one member on each committee selected from the Chicago area whom the staff head can frequently consult. This member shall be given the chairmanship unless another member has indicated by his special interest that he serve in such a capacity, or unless some other member is extremely prominent in his field or specialty.

The Board decided to make the appointments. Names on the suggested list plus names which the Board submitted at the time, were all given consideration. In general, committees were set up consisting of three men in each of the fields. In some cases, more than three names were submitted in the event that alternates would be needed.

Dr. Fishbein: The staff should arrange a time schedule for work on the revision. Closing dates must be established. I suggest that the committee report its last material not later than Dec. 1, 1949, so that the book can go to the printer in February 1950, and be ready for publication about June in time for presentation at the American Medical Association meeting in June and for the record librarians' meeting in the fall.

Dr. Baehr: I suggest that we go over the "International List" to see whether we have omitted anything in our index.

Mrs. Hayden: I suggest that the operative index should immediately follow the disease index.

Dr. Edwin L. Crosby, Baltimore: It is suggested that the index be extended because an adequate alphabetic index is one of the most important parts of such a book. Terms should be listed alphabetically according to diseases.

The members of the Board viewed the flexoline files which had been set up for work on the 1950 revision.

Both the "Nomenclature" file and the hospital file (though at present not completed) met with the approval of all the members.

The meeting was adjourned at 1 p. m.

## Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Chicago, Palmer House, Feb. 7-8. Dr. Donald G. Anderson, 535 N. Dearborn St., Chicago 10, Secretary.

Alaska Territorial Medical Association, Juneau, March 3-5. Dr. William P. Blanton, Box 2569, Juneau, Secretary.

American Academy of General Practice, Cincinnati, Netherlands Plaza Hotel, March 7-9. Mr. Mac F. Cahal, 231 W. 47th St., Kansas City, Mo., Executive Secretary.

American Association for Thoracic Surgery, New Orleans, March 29-31. Dr. Brian Blades, George Washington University Hospital, Washington, D. C., Secretary.

American College of Physicians, New York, March 28-April 1. Dr. George Morris Piersol, 4200 Pine St., Philadelphia 4, Secretary General.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, New York, Hotel Waldorf-Astoria, March 4. Dr. Norman N. Smith, 291 Whitney Ave., New Haven 11, Conn., Secretary.

Central Surgical Association, Cleveland, Hotel Cleveland, February 18-19. Dr. Walter G. Maddock, 250 E. Superior St., Chicago 11, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, Palmer House, March 1-4. Dr. H. Kenneth Scatliff, 30 N. Michigan Ave., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 14-17. Miss Thelma Webb, 1133 Medical Arts Bldg., Dallas, Executive Secretary.

Michigan Postgraduate Clinical Institute, Detroit, Book-Cadillac Hotel, March 23-25. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Mich., Secretary.

Missouri State Medical Association, Kansas City, March 27-30. Mr. T. R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Secretary.

National Conference on Medical Service, Chicago, Palmer House, February 6. Dr. John S. Bouslog, 1612 Tremont Place, Denver Colo., Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Municipal Auditorium, March 7-10. Dr. W. D. Beacham, 1430 Tulane Ave., New Orleans, Secretary.

Postgradute Assembly in Endocrinology, Association for the Study of Internal Secretions, Oklahoma City, Feb. 21-26. Dr. Henry H. Turner, 1200 N. Walker St., Oklahoma City 3, Secretary

# Washington Letter

*(From a Special Correspondent)*

Jan. 31, 1949.

## Health Bills Jam Hoppers of Senate and House

Approximately fifty medical research and public health bills were introduced in the first three weeks of the new Congress. All but five were filed, actually, in the first two weeks, the third week being that in which President Truman's inauguration was held and consequently one that witnessed few sessions of House or Senate.

Nine of the measures authorize a federally sponsored campaign of research in multiple sclerosis. Four are concerned with cancer and direct the President to mobilize world experts and conduct a $100,000,000 federal drive "to discover means of curing and preventing cancer." That efforts will be renewed in this Congress to create federal service positions for chiropractors is indicated by the early introduction of H. R. 1512, which authorizes their appointment in Veterans Administration. Its sponsor is Rep. Walter B. Huber (Democrat) of Akron, Ohio, who says he filed the bill at the request of the Veterans of Foreign Wars. It is similar to a measure introduced last year by Rep. James T. Patterson (Republican, Conn.) but which was pigeonholed in the Veterans Committee.

Ten Senators, led by Hill of Alabama, joined in introducing a bipartisan bill (S. 522) which provides for federal financial assistance to states and counties in development and improvement of local public health units. In content, it is the same as S. 132, introduced a few days earlier by Senator Chapman of Kentucky, except that it goes a step further and authorizes financial aid to public and nonprofit institutions offering training in public health. Senator Chapman is one of the cosponsors of S. 522.

Senator Johnson of Colorado introduced S. 458, which provides for a nationwide survey of physically handicapped persons. This measure was drafted by the American Federation of the Physically Handicapped, which also plans to support legislation on cerebral palsy, epilepsy and leprosy. Senators Pepper and Bridges are sponsors of a bipartisan bill to designate February 14 in each year as National Heart Week.

## Senate Labor and Public Welfare Committee

The Committee on Labor and Public Welfare of the Senate, as reconstituted for the Eighty-First Congress, held its first meeting on January 13. It is this committee, under chairmanship of Senator Elbert D. Thomas (Democrat, Utah), which will consider the Murray-Wagner-Dingell bill and handle most of the medical and public health legislation in this Congress. The thirteen member group is decidedly liberal in appearance, with Senators Thomas, Murray, Pepper, Douglas and Humphrey on the Democratic side and Senators Aiken and Morse among the Republican membership. Other members are Senators Hill and Neely, Democrats, and Taft, Smith and Donnell, Republicans. There is one vacancy on the committee, and it is expected to be filled by the new Senator from Kentucky, a Democrat, who will be appointed as successor to Vice President Barkley.

Not yet reorganized is the House Committee on Interstate and Foreign Commerce, which passes on virtually all health and medical legislation introduced in that branch of Congress prior to its transmittal to the floor for final action. Its chairman is Representative Robert Crosser (Democrat, Ohio). In the past, bills on compulsory sickness insurance have been referred to Ways and Means Committee, which have taken no action on them. This year, however, administration strategy apparently is to have Murray-Wagner-Dingell legislation handled on the House side by the Interstate and Foreign Commerce Committee, which already has received Representative John D. Dingell's (Democrat, Michigan) version of the measure. A companion measure sponsored by Representative Emanuel Celler (Democrat, New York) was sent to the Ways and Means Committee, but it is highly probable that the Dingell bill (H. R. 783) will be the administration's "bill of choice" if and when hearings are scheduled.

Among other newly introduced measures to be handled by the Senate Labor and the House Interstate committees are bills establishing a National Science Foundation (S. 247), authorizing a federal mental hospital in Alaska (H. R. 941) and permitting federal grants for construction of publicly and privately operated homes for the aged (H. R. 991).

## House Interstate Committee (Health Legislation) Organized

The first meeting of the newly formed House Interstate and Foreign Commerce Committee was scheduled for January 25, with indications that the twenty-eight member group would be divided into standing subcommittees for handling of special legislation. This is the committee that will consider and hold public hearings on all general health and medical research bills, including the Murray-Wagner-Dingell bill. Although in previous Congresses compulsory sickness insurance legislation has been referred to the Ways and Means Committee, it is known that the principal House sponsor, Representative John Dingell (Democrat, Michigan), is seeking to have the Interstate Committee take charge of the bill in the Eighty-First Congress.

The seventeen Democratic members of the committee are as follows: Robert Crosser (Ohio), chairman; Alfred L. Bulwinkle (N. C.), Lindley Beckworth (Texas), J. Percy Priest (Tenn.), Oren Harris (Ark.), George G. Sadowski (Mich.), Dwight L. Rogers (Fla.), Eugene J. Keogh and Arthur G. Klein (N. Y.), Thomas B. Stanley (Va.), John B. Sullivan (Mo.), William T. Granahan (Pa.), Andrew J. Biemiller (Wis.), John A. McGuire (Conn.), George H. Wilson (Okla.), Neil J. Linehan (Ill.) and Thomas R. Underwood (Ky.).

The eleven Republicans on the committee are: Charles A. Wolverton (N. J.), ranking minority member, who served as chairman in the Eightieth Congress; Carl Hinshaw (Calif.), Leonard W. Hall (N. Y.), Joseph P. O'Hara (Minn.), Wilson D. Gillette (Pa.), Robert Hale (Maine), Harris Ellsworth (Ore.), James I. Dolliver (Iowa), John W. Heselton (Mass.), Hugh D. Scott Jr. (Pa.) and John B. Bennett (Mich.).

All eleven Republicans were on the committee in the last Congress. On the Democratic side, additions are Representatives Klein, Stanley, Sullivan, Granahan, Biemiller, McGuire, Wilson, Linehan and Underwood.

## Inefficient Use of Scientists in Wartime is Subject of Report

The armed services made poor use, on the whole, of scientists in uniform during World War II, according to a study just published by Department of the Army. Based on answers to questionnaires filled out by 15,157 scientists and engineers who served in the armed forces as officers and enlisted men, the report was prepared by David M. Delo, chief of scientific man power in the Army's logistics division. Scientists whose professional skills were employed to best advantage were psychologists, geographers, engineers and physicists, in that order. Those most poorly utilized were biologists, geologists, chemists and mathematicians, in that order. Recommendations are made to the end that optimal employment of scientists may be achieved by the armed services in the future, but the report emphasizes that "adequate numbers of physicians and supporting personnel such as radiologists, bacteriologists and sanitary engineers must be reserved in civilian status to maintain the national health" in event of another war.

## American Red Cross Sends Measles Globulin to Hawaii

American Red Cross headquarters in Washington has announced shipment of 3,000 units of immune serum globulin to combat a measles outbreak in Hawaii. It was flown from San Francisco to Honolulu and brought to 11,000 units the total quantity shipped during the last few months. According to the Red Cross, the Honolulu Board of Health attributes the low death rate in the measles epidemic to use of the globulin.

# Medical Legislation

## STATE LEGISLATION

### Arizona

**Bill Introduced.**—H. 1 proposes to vest in the State Department of Health administration of the program of **service for crippled children** and proposes to make it the duty of such department to, among other things, provide for medical, surgical, corrective and other services and care, and facilities for diagnosis, hospitalization and aftercare.

### Arkansas

**Bill Introduced.**—H. 23 proposes the creation of a **financing board for Arkansas medical students** and to direct such board to prescribe appropriate forms for loan applications and to prescribe reasonable rules and regulations to carry out the purposes of the act, namely, to assist in financing medical students who need aid in order to complete their education.

### California

**Bills Introduced.**—A. 165, **to amend the labor code,** proposes to entitle an employee to all medical services at the expense of the employer. A. 191, **to amend the labor code,** proposes to authorize the appointment by the Industrial Commission of a medical director, who shall be licensed to practice medicine in the state. A. 252 proposes to make it a misdemeanor for any person **to perform an autopsy** on a dead body without having first obtained the written authorization of the coroner or other authorized public officer, or the person who has the right of disposition of the body. A. 259, to amend the health and safety code **relating to hospital districts,** proposes that no person shall be excluded from any hospital district because his or her attending physician and surgeon is a member of any particular school of practice so long as the attending physician is licensed as a physician and surgeon under the provisions of Chapter 5, Division 2, of the Business and Professions Code, provided, however, that the provision of this section shall not prohibit the board from denying to any physician and surgeon the right to practice in any hospital under their management for cause arising from his professional conduct or ethics. A. 310, **to amend the labor code,** proposes that all medical records, pictures or other pertinent data in the hands of or under the control of the employer or his representative shall be made available to any consulting or attending physician without cost to the employee. A. 481, to amend the business and professions code, proposes to require the **pathologists** in each hospital in the state **to prepare slides of all tissues removed** from patients in that hospital and to send such slides to the Board of Pathology for examination. The board would be required to examine all such slides. The proposal then would provide that the removal of normal tissues on six occasions within any six months would constitute unprofessional conduct on the part of the pathologist. A. 514 proposes the creation of a **State Board of Audiometry** which is defined as the measurement of the powers or range of human hearing and the prescribing, fitting or selling of hearing aids. A. 523, to amend the business and professions code, proposes that any person who has been licensed as a physician and surgeon by either the Board of Medical Examiners or the Board of Osteopathic Examiners, but not both boards, and who holds the degrees of doctor of medicine and doctor of osteopathy from a school of medicine and a school of osteopathy, **must use both titles** or abbreviations thereof in connection with his name. A. 555 proposes to authorize the board of medical examiners to grant licenses for **the practice of physical therapy,** which is defined as the treatment of any bodily or mental condition of any person by the use of the physical, chemical, and other properties of heat, light, water, electricity, massage, and active and passive exercise. The use of roentgen rays and radium for diagnostic and therapeutic purposes, and the use of electricity for surgical purposes, including cauterization, are not authorized under the term "physical therapy" as used in this proposal. S. 11, **to amend the business and professions code,** proposes to define the practice of optometry as, among other things, the prescribing and directing of ocular exercises, visual training, vision training, orthoptics, and any other methods for the aid or improvement of human vision and the prescribing of contact lenses for, or the fitting or adaptation of contact lenses to the human eye. S. 16 and S. 72, **to amend the business and professions code,** propose to authorize the board of osteopathic examiners to issue a physician's and surgeon's certificate. S. 36, **to amend the business and professions code,** proposes that any physician and surgeon whose name appears on an eligible list for state civil service is not required to hold a physician's and surgeon's certificate in order to practice medicine as an employee of the state within state institutions, prisons or homes. S. 117 proposes the creation of a **Board of Physical Therapy** Examiners and defines the term "physical therapy" as meaning "the performing for compensation, received or expected, of any professional service requiring special education, knowledge or skill, in the treatment or alleviation of any human ailment, deformity, fatigue, disease, injury, pain, or other physical or mental condition, by physical means, including the various 'modalities' of electricity (except x-ray, radium and electrosurgery), light, heat, water, exercise and therapeutic massage." Therapeutic massage is defined as meaning "the kneading, rubbing and massaging of the human body, whether with or without such appliances as steambaths, vapor-baths, electric light baths, electric vibrators or any other similar methods, but does not include any use of electricity for therapeutic purpose except the use of electric light baths and electric vibrators. S. 125 proposes the enactment of a Licensed **Practical Nurse Act** and defines nursing as "such nursing duties as are required in the physical care of a patient in carrying out of medical orders as prescribed by a licensed physician, requiring an understanding of nursing skills, but not requiring the professional nursing services as defined in the Nursing Practice Act." S. 131, **to amend the education code,** proposes that a supervisor of health report to the parent or guardian shall not include any recommendations suggesting or directing the pupil to a designated individual or class of practitioners for the purpose of curing any defect referred to in the report. S. 157 proposes the enactment of a **California prepaid health service** act. S. 203 proposes to authorize the State Board of Health to grant **permits for the use of x-rays** or radiographs by individuals and makes it unlawful for persons not possessing such a permit to make use of the x-ray device or to operate x-ray laboratories.

### Georgia

**Bill Introduced.**—S. 19 proposes to amend the hospital service plan enabling act so as to permit the creation of **nonprofit medical service plans.**

### Illinois

**Bills Introduced.**—S. 19 proposes the creation of an Illinois State Alcoholics Hospital for the treatment and care of **persons afflicted with alcholism.** S. 21 proposes the creation of a Commission on Professional and Vocational Standards to make a survey of all regulatory measures relative to vocations, professions and semiprofessional vocations concerning existing qualifications, together with qualifications that are desired by various professional and vocational groups to raise their standards and to improve their specialized talents.

### Indiana

**Bill Introduced.**—S. 50 proposes the creation of an Indiana State **Board of Nurses Registration** and Nursing Education and provides for the licensing of nursing which is defined to mean "any person who for compensation or personal profit (a) as a registered nurse performs any professional services requiring the application of principles of the biological, physical and social sciences, and nursing skills in the care of the sick, in the prevention of disease or in the conservation of health or (b) as a licensed practical nurse performs such duties as are required in the physical care of a convalescent, a chronically ill and an aged or infirm patient and in carrying out of medical orders as prescribed by a licensed physician, requiring a knowledge of simple nursing procedures but not requiring the professional knowledge and skills required for professional nursing."

### Iowa

**Bills Introduced.**—H. 60 proposes the enactment of an Iowa Drug and Cosmetic Act which would provide, among other things, that a drug **shall be deemed to be misbranded** if sold at retail and containing any quantity of aminopyrine, barbituric acid, pituitary, thyroid, or their derivatives unless it is sold on a written prescription signed by a doctor, dentist or veterinarian who is licensed by law to administer such drug or device and its label bears the name and place of business of the seller, the serial number and date of such prescription, and the name of the doctor, dentist or veterinarian. In general, this bill contains all the provisions of the uniform food, drug and cosmetic act. S. 103 proposes amendments to the nursing act for the purpose of **licensing practical and registered nurses.** This proposal would provide that any person shall be deemed to be engaged in the practice of nursing as a practical nurse who performs such duties as are required in the physical care of a convalescent, a chronically ill or an aged or infirm patient, and in carrying out such medical orders as are prescribed by a licensed physician or nursing services under the direct supervision of a registered nurse, requiring the knowledge of simple nursing procedures but not requiring the professional knowledge and skills of a registered nurse.

### Massachusetts

**Bills Introduced.**—H. 64 and S. 127 propose to authorize school committees to establish, maintain and operate **school lunch programs** in accordance with the provisions of the National School Lunch Act. H. 102, relating to the development of a state hospital construction program, **proposes to define hospital** so as to include public health centers and general, tuberculosis, mental, chronic disease and other types of hospitals and related facilities, such as laboratories, outpatient departments, nurses' homes and training facilities and central service facilities operated in connection with hospitals, but shall not include any hospital primarily furnishing domiciliary care. A proposal also provides for the creation of an advisory hospital council to advise and consult with the department of public health in the administration of the act. H. 193 proposes the creation of a special commission to investigate the conditions in the department of **mental health and hospitals** under its supervision, including the financial management of such hospitals, the food, care, treatment of inmates and employees of such hospitals, improper detention of inmates who are not in need of hospitalization and other matters. H. 194 proposes the creation of a special commission for the purpose of making a study of **the cancer problem** within the commonwealth. H. 226 and H. 435 propose to direct the University of Massachusetts to immediately establish **schools of medicine.** H. 513, to amend the law relative to operating a **motor vehicle** while under the **influence of liquor,** proposes that any person who is held in custody and charged with operating a motor vehicle while under the influence of liquor shall be permitted to use a telephone, at his own expense, for the purpose of calling a physician of his own choice to make an examination of his condition. H. 1442 proposes that any **tax-exempt medical,** dental or pharmaceutical **college,** and other types of institutions, shall be subject to the following regulation: students shall not be admitted or denied admittance in accordance with any quota system based on race, creed, color, national or regional origin, places in each entering class shall be open to the most qualified students chosen in order of their rank by process of open examination, and examination questions and grades shall be on file and checked by the state commissioner of education. S. 45, to amend the law relating to evidence, proposes to authorize the admission in evidence of **microphotographic film** in all instances that the original record thereof would have been admitted.

# GOVERNMENT SERVICES

## ARMY

### CONSULTANTS TO THE PANAMA COMMAND IN 1948-1949

The Surgeon General's Office has been carrying out a program designed to bring to the Army Medical Department in the Panama Area the latest advances in the field of medicine and in so doing assigned during 1948-1949 the following civilian consultants to aid in this work:

| Name | Residence | Specialty |
|---|---|---|
| | OCTOBER 1948 | |
| Conn, Jerome W. | Ann Arbor, Mich. | Internal medicine |
| Kimbrough, James J., Col. | Washington, D. C. | Urology |
| | NOVEMBER 1948 | |
| Bennett, Granville A. | Chicago | Pathology |
| Poor, David H. | Atlanta, Ga. | General surgery |
| | DECEMBER 1948 | |
| Heilbrun, Norman | Buffalo | Radiology |
| | JANUARY 1949 | |
| Miller, Don A. | Warren, Ohio | General surgery |
| Most, Harry | New York | Medicine |
| Vail, Derrick | Chicago | Ophthalmology |
| | FEBRUARY 1949 | |
| Nesbit, Reed M. | Ann Arbor, Mich. | Urology |
| | MARCH 1949 | |
| Berry, Frank B. | New York | General surgery |
| | APRIL 1949 | |
| Ball, Robert P. | New York | Radiology |
| | MAY 1949 | |
| Elkin, Daniel C. | Emory, Ga. | General surgery |
| Simpson, G. Victor | Washington, D. C. | Ophthalmology |
| | JUNE 1949 | |
| Brown, Thomas McP. | Washington, D. C. | Medicine |
| Curtis, W. R. | El Paso, Texas | Urology |

### POSTGRADUATE INSTRUCTION

The following medical corps officers have been accepted by the civilian institutions indicated for postgraduate instruction: Lieutenant Colonels George B. Green, course in therapeutics, George Washington University, Washington, D. C., and George M. Plagens, course in psychiatry, George Washington University, Washington, D. C.; Captain Walter B. Watson, residency in pediatrics, Babies Hospital–Coit Memorial, Newark, N. J.; First Lieutenants Harry D. Arnold, course in ophthalmology, Fulton-DeKalb Hospital Authority, Atlanta, Ga.; Arthur J. Crumbley, course in surgery, Grady Memorial Hospital, Atlanta, Ga.; David J. Hughes, residency in medicine, Grady Memorial Hospital, Atlanta, Ga.; Charles H. Lasley, course in surgery, Grady Memorial Hospital, Atlanta, Ga.; Fred D. Ownby, course in pathology, Emory University, Emory University, Ga., and Harold L. Wilkins, internship in medicine, Boston City Hospital, Boston.

### ARMY MEDICAL LIBRARY

The Surgeon General has appointed the following additional honorary consultants to the Army Medical Library: Dr. Raymond B. Allen, President, University of Washington; Dr. Chester N. Frazier, professor of dermatology, Harvard University; Richard H. Shyrock, professor of American history, University of Pennsylvania, and George Urdang, professor of history of pharmacy, University of Wisconsin.

The agent of the Army Medical Library in Japan has just cleared the necessary paths for export from that country, and his first shipment of recent Japanese medical books is expected at any time. Two cases of journals and books supplied on an exchange basis have just been received, and among these are all of the issues needed to complete the files of the various sections of the *Japanese Journal of Medical Sciences.*

### PERSONALS

Major General Raymond W. Bliss, Surgeon General, was awarded an honorary fellowship at the annual congress of the American College of Surgeons in Los Angeles. General Bliss has been a fellow of the College for many years. In 1920 he took a special course in surgery at Harvard Medical School, and subsequently was chief of surgery at Sternberg General Hospital in Manila, at Fort Sam Houston, Texas, and at the William Beaumont General Hospital, El Paso, Texas. During the recent war, he was chief of operations in the Surgeon-General's Office, later becoming Assistant Surgeon General, then Deputy Surgeon General, and on June 1, 1947, Surgeon General of the Army.

Major Edward J. Dehne, M.C., has been decorated with the Order of Leopold II by the Belgian Government in recognition of his wartime services in the European Theater as a public health specialist. Major Dehne is now chief of the medicine section of the Army Industrial Hygiene Laboratory at the Army Chemical Center in Maryland.

## VETERANS ADMINISTRATION

### CANCEL 24 NEW HOSPITAL PROJECTS

The Administrator of Veterans Affairs, Carl R. Gray Jr., announces that a study of the hospital expansion program has shown that the estimated needs for hospital beds made immediately after the war were considerably larger than has proved necessary and that the President has ordered a reduction of 16,000 beds. To effect this, the Veterans Administration plans the cancellation of twenty-four new hospitals and a reduction in the size of fourteen others; none of these hospitals is beyond the planning stage. The Veterans Administration currently has thirty-one new hospitals in various stages of construction. Mr. Gray indicated that even under the curtailed program the Veterans Administration will be able to admit an even larger proportion of non-service-connected patients than at present. The principal reasons for cancellation of proposed construction are: (1) inability of the Veterans Administration fully to staff its present hospitals and a further definite shortage of professional personnel to staff new hospitals; (2) estimated possible maximum load of service-connected patients is 51,000, leaving more than twice as many other beds available to other veteran patients; (3) temporary hospitals taken over from the armed forces at the end of the war are remaining serviceable beyond original estimates and will not need immediate replacement as had been contemplated, and (4) the delay will give the Veterans Administration a full opportunity, in the light of experience with World War II patients, to develop further a program which meets the lasting needs of all veterans.

At present, the Veterans Administration has 110,433 beds in its own hospitals, but, because of lack of doctors, nurses, technicians and other personnel, operates only 103,533 beds with about 93,000 patients. In emphasizing the problem of staffing new hospitals, Mr. Gray declared that recent experience had demonstrated the necessity of locating new hospitals in places where professional resources are available. He said that elimination of the proposed new beds would result in a saving of $280,000,000.

The hospitals scheduled to be eliminated under terms of the President's order are:

| Location | Type | Beds |
|---|---|---|
| New York | Rehabilitation | 1,000 |
| Harrisburg, Pa | General medical | 200 |
| Charlotte, N. C | General medical | 500 |
| Salisbury, N. C | Neuropsychiatric | 921 |
| Americus, Ga | Tuberculosis | 250 |
| Chattanooga, Tenn | General medical | 500 |
| Gainesville, Fla | Neuropsychiatric | 1,000 |
| Greenville, S. C | General medical | 200 |
| Memphis, Tenn | Neuropsychiatric | 1,000 |
| Tallahassee, Fla | General medical | 100 |
| Thomasville, Ga | General medical | 100 |
| Grand Rapids, Mich | General medical | 200 |
| Toledo, Ohio | Neuropsychiatric | 1,000 |
| Decatur, Ill | General medical | 250 |
| Duluth, Minn | General medical | 200 |
| Norman, Okla | Neuropsychiatric | 750 |
| El Paso, Texas | Neuropsychiatric | 500 |
| Houston, Texas | Neuropsychiatric | 1,000 * |
| Mound Bayou, Miss | General medical | 200 |
| Tupelo, Miss | General medical | 200 |
| Klamath Falls, Ore | General medical | 200 |
| San Diego, Calif | General medical | 200 |
| Columbia, S. C | General medical | 200 † |
| Detroit | Tuberculosis | 500 |

* Cancelled, with beds replaced by the Veterans Administration's taking over Houston U. S. Naval Hospital.

† Addition.

Projects to be altered in size from the present plans are:

| Location | Type | Beds From: | Beds To: |
|---|---|---|---|
| Syracuse, N. Y | General medical | 1,000 | 500 |
| Philadelphia | General medical | 1,000 | 500 |
| Pittsburgh | General medical | 1,200 | 750 |
|  | Neuropsychiatric | 1,250 | 1,000 |
|  | General medical | 750 | 500 |
| Atlanta, Ga | General medical | 750 | 500 |
| Cincinnati | General medical | 750 | 500 |
| Cleveland | General medical | 1,000 | 500 |
| Cleveland | Neuropsychiatric | 1,250 | 1,000 |
| Louisville, Ky | General medical | 750 | 500 |
| Chicago | General medical | 1,000 | 500 |
| Kansas City, Mo | General medical and tuberculosis to all tuberculosis | 745 | 500 * |
| New York | General medical | 1,000 | 1,250 |
| Oklahoma City | General medical | 1,000 | 500 |
| St. Louis | General medical | 1,000 | 500 |

* Originally planned for 495 general medical and 250 tuberculosis beds; now 500 tuberculosis beds.

## THE TRAINING OF HOSPITAL MANAGERS

The Veterans Administration announces the establishment of an *institute to train newly appointed hospital* managers in policies and procedures of Veteran Administration hospital management. Some twenty persons are expected to attend the four weeks' session to be held in the Veterans Administration's Central Office in Washington, D. C. On completing the course, the "students" will be assigned for one month's duty at the hospitals of the five instructors. At the end of the month, they will return to their respective hospitals. The institute will cover legal medicine, hospital maintenance, public relations, public speaking, hospital planning, personnel management and other topics. Lectures by authorities in these fields will be followed by workshop roundtables and discussions. The institute is expected to be repeated semiannually.

## OUTPATIENT TREATMENT OF VETERANS

Nearly 2,000,000 veterans received outpatient treatment during the fiscal year ending June 30, 1948. The treatments were given by the Veterans Administration at regional offices, hospitals and clinics, and by private physicians cooperating with the Veterans Administration in providing "home town" care for veterans with service-connected disabilities. Treatments averaged 3 per veteran, or a total of 5,233,680. Private physicians treated 761,185 veterans, or about 40 per cent of the total. The physicians were paid $11,437,870 for 2,735,450 treatments, for an average of $4.18 per treatment or $15.03 per veteran undergoing medical care. Veterans Administration staff doctors during the year treated 1,176,657 individual veterans and provided a total of 2,498,230 treatments.

## HOSPITAL NEWS

Sealed bids are being accepted for the construction of a 500 bed general hospital for the Veterans Administration at Indianapolis including, in addition to the hospital building, nurses' quarters, an apartment building for staff members, manager's quarters, attendants' quarters and other buildings.

# PUBLIC HEALTH SERVICE

## OUTBREAK OF YELLOW FEVER IN PANAMA

For the first time since 1905 an outbreak of yellow fever has occurred in the Republic of Panama, with 8 cases and 6 deaths, as of January 19, in and about Pacora, about 22 miles from Panama City. The National Institutes of Health of the U. S. Public Health Service have donated and sent to Panama a quarter-million doses of yellow fever vaccine which came from the Rocky Mountain Laboratory of the institutes at Hamilton, Mont. The first shipment of 75,000 doses was sent by Air Force plane direct from Montana January 16, and the second shipment of 175,000 doses was flown by commercial plane from Montana to New York and then sent by boat to Panama. The Panama Canal office in Washington also arranged for the shipment of 1,000 blood-collecting tubes from Walter Reed Hospital which were contributed by the Army.

## FLUORIDE DEMONSTRATION TEAMS IN 26 STATES

Thirty-four states and all the territories have requested the assignment of topical fluoride demonstration teams; and teams are already at work in twenty-six states, Alaska and the District of Columbia, demonstrating the technic of application of sodium fluoride to the teeth and showing how a topical fluoride program can be organized on a community basis. The Eightieth Congress authorized $1,000,000 for a program which provided for the organization at the request of state health departments of demonstration units composed of a dentist, two dental hygienists and a clerk. According to the Public Health Service, the stimulus for the program grew out of the discovery that a solution of sodium fluoride will curb decay in children's teeth by an average of 40 per cent. Following is the list of states and territories which already have been assigned demonstration teams:

Alaska
Arkansas
Colorado
Connecticut
Delaware
District of Columbia
Florida
Illinois
Indiana
Kansas
Maine
Maryland
Massachusetts
Michigan
Missouri
Nevado
New Hampshire
New York
North Dakota
Oklahoma
Pennsylvania
Rhode Island
South Carolina
Tennessee
Virginia
Washington
West Virginia
Wyoming

## POSTGRADUATE INSTRUCTION

The following public health officers have been assigned to the institutions indicated for postgraduate instruction: Surgeon Robert W. Rasor in training at the Chicago Institute for Psychoanalysis; Senior Assistant Surgeon Gove Hambidge Jr. in training at Columbia University School of Psychoanalysis; Senior Assistant Surgeon Robert L. Faucett in training as a resident in psychiatry at the University of Minnesota, Minneapolis; Assistant Surgeon Robert H. Dysinger in training at the Bellevue Hospital, and Assistant Surgeon John P. Utz in training in biochemistry at the Graduate School of Georgetown University.

## PERSONAL

Dr. Paul Chanson, of the National Center of Scientific Research, Bellevue, France, has arrived at the National Institutes of Health, Bethesda, Md., for a six month research fellowship. He will work in the Laboratory of Physical Biology with Dr. R. W. C. Wyckoff on the design of special lenses for the electron microscope.

# Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

## ALABAMA

**Alabama Doctors Overwhelmingly Disapprove Compulsory Health Insurance.**—The Medical Association of the State of Alabama through its Committee on Medical Service and Public Relations recently wrote a letter to every doctor in the state, whether or not a member of the association, asking him to state whether he approved or disapproved the proposed National Compulsory Health Insurance. Replies were received from 1,306 doctors, or two thirds of those who received the letter. Of this number 96 per cent voted disapproval of the National Compulsory Health Insurance and 2.3 per cent approved; 1.3 per cent returned their ballots without voting, and 0.4 per cent answered in such a manner that the ballot could not be classified.

The Committee on Medical Service and Public Relations of the state medical association also voted approval of the following program for the betterment of medical service: (1) direct appropriations for the building of hospitals and clinics in sparsely settled areas; (2) enlargement of the medical school facilities for the education of more doctors, nurses, dentists and technicians; (3) the extension of voluntary insurance coverage to all classes of people and extension to the indigent groups through appropriations by local and state governing bodies; (4) inspecting, grading and licensing of hospitals and clinics for the purpose of improving the medical staffs and hospital facilities and services, and (5) plans for the care of old age and destitute persons, perhaps through nursing homes.

## ARKANSAS

**Course in Pediatrics.**—A postgraduate course in pediatrics will be given by the department of pediatrics, University of Arkansas School of Medicine, Little Rock, March 11-12 from 9 a. m. to 5 p. m. Guest speakers will be Drs. James G. Hughes, associate professor of pediatrics, University of Tennessee, Memphis, Tenn., and Dr. Myron E. Wegman, professor of pediatrics, Louisiana State University, New Orleans. Physicians interested are invited to attend and to notify Dr. William A. Reilly at the University of Arkansas School of Medicine, Little Rock.

## CALIFORNIA

**Gift to Hospital.**—A 2 acre country estate including a fourteen room house and cottage has been presented to the Cedars of Lebanon Hospital, Los Angeles, by Al Jolson, according to newspaper reports. The property, valued at $160,000, will probably be sold and the money devoted to financing a 100 bed wing at the institution.

**Society News.**—At the annual meeting of the San Francisco County Medical Society in December Dr. Ivan C. Heron was elected president and Dr. M. Laurence Montgomery was reelected secretary-treasurer and editor of the *Bulletin.*——The Los Angeles County Medical Association in December elected Dr. Benjamin M. Frees president and Dr. Richard O. Bullis secretary-treasurer.

**Fifty Year Practitioners.**—At the seventy-ninth annual meeting of the Alameda County Medical Association in Berkeley November 15, tribute was paid to ten doctors in a program which was presented as "A Night in '98." Those doctors honored were Drs. Kirby B. Smith, William B. Stephens, Edward Norton Ewer, Hayward G. Thomas, Manuel M. Enos, Murrey L. Johnson, Edward S. DePuy, Henrich W. Kohlmoos, Eva L. Harris and Clara M. Holmes-Brazelton.

## COLORADO

**Penrose Cancer Hospital.**—A part of the facilities of the Glockner-Penrose Hospital, Colorado Springs, including its richly endowed radiotherapy department and a number of hospital beds, is to be reserved for use by cancer patients and will be known as the Penrose Cancer Hospital. Dr. Juan A. del Regato, formerly associated with the Ellis Fischel State Cancer Hospital of Columbia, Mo., has been appointed director. Dr. del Regato is a graduate of the Université de Paris Faculté de Médecine, 1937, and received his training in radiotherapy at the Foundation Curie of Paris. The Penrose Cancer Hospital expects to coordinate and stimulate the efforts of the members of the medical staff, centralizing the facilities for the diagnosis and treatment of cancer; the organization of the medical work on a high scientific standard should provide enviable opportunities for training of young physicians in the diagnosis and treatment of cancer. This will fulfil the wishes of the late Spencer Penrose and achieve the favorite project of his widow, Mrs. Julie Penrose of Colorado Springs.

## CONNECTICUT

**Committee on Emergency Medical Service.**—The Connecticut State Medical Society's council has announced formation of a Committee on Emergency Medical Service to augment the work being done by the national committee of the American Medical Association in planning defense for the civilian population in event of national emergency. The committee is headed by Dr. William B. Smith, Hartford, and its members are Drs. C. Frederick Yeager, Bridgeport; Orpheus J. Bizzozero, Waterbury; George M. Smith, Pine Orchard, and Benjamin B. Whitcomb, Hartford. Other members will soon be appointed to represent the Connecticut State Department of Health, the Connecticut Nurses' Association and the Connecticut Hospital Association.

**Connecticut Medical Service Elects Officers.**—Robert S. Judd, New Haven, was elected chairman of the twelve member Board of Directors of Connecticut Medical Service at a recent organization meeting of the new nonprofit medical care plan adopted by the state medical society's house of delegates last December (The Journal, Dec. 25, 1948, p. 1246). Mr. Judd is director and first vice president of the Grace-New Haven Community Hospital and vice president of the Southern New England Telephone Company. Other officers include Drs. Joseph H. Howard, Bridgeport, vice president; Louis F. Middlebrook, Hartford, secretary, and George R. Willis, New Haven, treasurer. Dr. Creighton Barker, executive secretary of the state medical society, was appointed acting director.

## ILLINOIS

**Community Honors Dr. Whited.**—More than 1,000 persons on January 8 gathered at the home of Dr. David F. Whited, Dahlgren, to honor the doctor, who has practiced in that community for fifty years, on the occasion of his seventy-sixth birthday. More than 2,000 contributors made possible the presentation to Dr. Whited of a new business coupé and a gold watch, and to Mrs. Whited a complete living room suite. Dr. Andy Hall, Mt. Vernon, made the presentation speech, lauding Dr. Whited for his unselfish service to the people of this area.

### Chicago

**Prenatal Nutrition Service.**—Chicago Health Department nutritionists now present diet information for mothers' classes at three prenatal clinics in the city. Individual advice to expectant mothers with special nutritional problems is also given. The average monthly attendance at the three clinics is 125, with 30 new cases a month. The nutritional instruction is free of charge to women who do not have a private physician.

**Personal.**—Paul L. Munson, formerly head of endocrinology research for Armour and Company, has been appointed research assistant professor in the department of pharmacology, Yale University School of Medicine, New Haven.——John S. Laughlin, Ph.D., who has been associated with the cyclotron and betatron projects at the Urbana campus of the University of Illinois, has been appointed assistant professor of radiology and radiation physicist at the University of Illinois College of Medicine, Chicago.

**Grants for Research.**—The University of Illinois College of Medicine has received five research grants totaling $14,346. The largest of these, $5,346, was a grant from Eli Lilly and Company of Indianapolis for studies in mumps vaccination. Other grants were: $3,500 from the LaRabida Jackson Park Sanitarium for the study of rheumatic fever; $3,000 from the G. D. Searle Company, Chicago, for research on bronchial asthma; $2,000 from Smith, Kline and French, Philadelphia, for the study of the effect of amines in experimental renal and other hypertensions, and $500 from the Commonwealth Fund for a study of nucleic acid.

**Appointments to Northwestern Faculty.**—Three appointments have been made to the Northwestern University Medical School faculty. Dr. Paul A. Campbell, a graduate of Rush Medical College and a former member of the faculty of the University of Illinois, has been appointed assistant professor of otolaryngology. Dr. Anna Hamann, a graduate of the University of Munich medical school and a member of the University of Chicago faculty, has been appointed assistant professor of radiology. Dr. Robert Shrek, since 1941 chief of the Tumor

Research Unit of Hines (Ill.) Veterans Administration Hospital, has been appointed assistant professor of pathology. He served in the Medical Corps from 1942 to 1944 and has been assistant in pathology at Yale University.

## INDIANA

**Fifty Year Club.**—At the first anniversary meeting of the Fifty Year Club of the Indiana State Medical Association, thirty-eight Indiana physicians became members of the club, making the present total membership 242.

**General Practitioner Meeting.**—The first scientific session of the Indiana Academy of General Practice will be held in Indianapolis February 9. All members of the Indiana State Medical Association are invited to attend both the afternoon and dinner meetings. The program beginning at 1:30 p. m. in the auditorium of the Indiana University School of Medicine is as follows:

Virgil McCasty, Princeton, Appendicitis in the Small Hospital.
John D. Van Nuys, Indianapolis, Educational Requirements of Undergraduates and Graduates in General Practice.
Walter L. Portteus, Franklin, Economics of General Practice.

At the general meeting Dr. Walter C. Alvarez, Rochester, Minn., will speak on "Puzzling Functional Troubles Found in Practice."

## MINNESOTA

**The Kenny Institute.**—The Sister Kenny Institute in Minneapolis, founded in 1942 at the Lymanhurst Hospital, has undergone a reorganization of its staff. With the appointment of Dr. Edgar J. Huenekens, pediatrician of Minneapolis, as chief of staff of the institute last August, the addition of Dr. Miland E. Knapp as chief of physical medicine in charge of treatment and training of physical therapists, also of Dr. John F. Pohl as consulting orthopedic surgeon, Dr. Sigsbee R. Seljeskog and others, the institute is assured of first class professional supervision.

## NEW HAMPSHIRE

**New Orthopedic Clinic.**—The Hitchcock Clinic and the Division of Crippled Children's Services of the New Hampshire State Department of Health are cooperating in holding an orthopedic clinic at the Hitchcock Clinic in Hanover. The clinic will be held on the fourth Friday of each month, from 8:30 to 10:30 a. m. Cases will be limited to 15 for the time being. Appointments are to be made at least one week in advance through Mr. Allen E. Howland, executive secretary, Hitchcock Clinic, Hanover. In addition to orthopedic services, consultation for plastic and neurologic defects will be available on referral. There is no fee. Persons under 21 years of age will be accepted.

## NEW YORK

**Postgraduate Lectures.**—The Medical Society of the State of New York in cooperation with the New York State Department of Health has arranged for a joint meeting of the Richmond County Medical Society and its Woman's Auxiliary March 9, 9 p. m., at Atlantic Inn, Staten Island. Dr. Louis H. Bauer, Hempstead, Long Island, will speak on "Socialized Medicine." The Clinton County Medical Society will hear Dr. Howard T. Behrman, New York, speak on "Modern Treatment of Skin Diseases" March 17, 8:30 p. m., at the Champlain Valley Nurses' Home, Plattsburg.

**Personals.**—Drs. Margaret M. Janeway, New York, and Thomas A. McGoldrick, Brooklyn, have been appointed by Governor Dewey as medical representatives on the State Industrial Council. Dr. Janeway will serve a full three year term and Dr. McGoldrick will fill the unexpired term of Dr. Nathan B. Van Etten, recently resigned. The council acts in an advisory capacity to the state industrial commissioner.——Dr. Howard McC. Snyder, member of the committee to the President of the U. S. on Integration and Improvement of the U. S. Medical and Hospital Services since May 1946, has been named special consultant to the New York State Hospital Study now being carried on at Columbia University under the direction of Associate Professor Eli Ginzberg, Ph.D.

**Celebrate Anniversary of Dr. Blackwell's Graduation.**—Hobart College, Geneva, at a special convocation January 23 celebrated the hundredth anniversary of the graduation of Elizabeth Blackwell, first woman to receive a degree of doctor of medicine. Citations were made to ten leading women doctors of the United States and Canada for their own achievements in their profession. Nominations for these citations were made by the deans of the class A medical colleges of the United States and Canada. The women cited are: Drs. Florence R. Sabin, Denver; Alice Hamilton, Hadlyme, Conn.; Helen B. Taussig, Baltimore; Martha May Eliot, Washington, D. C.; Gerty Cori, St. Louis; Priscilla White, Boston; Helen V. McLean, Randolph Center, Vt.; Margaret D. Craighill, Topeka, Kan.; Helen MacMurchy, Toronto, Canada, and Elise S. L'Esperance, New York.

### New York City

**Dr. Sonneborn to Give Harvey Lecture.**—Tracy M. Sonneborn, Ph.D., professor of zoology, Indiana University, Bloomington, will deliver the fifth Harvey Lecture of the current series at the New York Academy of Medicine February 17 on "Cellular Transformation."

**Tuberculosis Conference.**—The annual Conference of the New York Tuberculosis and Health Association will be held March 8 at the Hotel Statler. Authorities on various phases of tuberculosis work, social hygiene and health education will present papers. Election of officers of the Tuberculosis Sanatorium Conference of Metropolitan New York, which will meet simultaneously, also will be held.

**Forum on Problems of Deafness.**—The Otolaryngology Section of the New York Academy of Medicine will join the New York League for the Hard of Hearing February 16 in a public symposium at the New York Academy of Medicine, 8:15 p. m. Subjects under discussion include The Patient: Emotional Factors in Young and Old, Training the Child for Speech and Hearing, Guidance and Training of Parents, Tests and Testing, and Prevention, Management and Treatment.

**Fifty Years of Service.**—Five doctors, each of whom has practiced fifty years in the community, were honored at a banquet January 22, attended by the Board of Trustees of Lebanon Hospital. The doctors, all members of the hospital staff, are Henry Roth, honorary director of surgery; Abraham J. Rongy, attending obstetrician and gynecologist; Sidney V. Haas, pediatrician; Moses D. Lederman, consulting aural and laryngologic surgeon, and William Weinberger, attending physician.

**Increase City Payment to Tuberculosis Hospitals.**—The Board of Estimate has voted to increase the city's payment to hospitals treating tuberculosis patients from $5 to $7.50 a day, which will increase annual hospital income by $163,000. At the same time the board made available $501,775 for an additional three hundred beds for tuberculosis patients, one hundred to be made available to the Stony Wold Sanatorium in the Adirondack Mountains at the rate of $6.25 a day and two hundred allocated to general hospitals at the rate of $7.50 a day. This is expected to help ease the overcrowding in city institutions.

**Advanced Course in Rehabilitation Methods.**—A special advanced course in rehabilitation methods for physical therapists is to be conducted by the Institute of Rehabilitation and Physical Medicine of the New York University-Bellevue Medical Center in conjunction with the New York University School of Education. Instruction will be given under the supervision of Drs. Howard A. Rusk, George G. Deaver and Donald A. Covalt, all of New York University College of Medicine, and Miss Edith Buchwald and Miss Beth Addoms of the New York University School of Education. The first of the series of courses will run from February 9 to March 22 and April 4 to May 13. Information can be obtained by writing Miss Edith Buchwald, Director, Rehabilitation Courses for Physical Therapists, Institute of Rehabilitation and Physical Medicine, 325 East 38th Street, New York 16.

## NORTH DAKOTA

**License Limited Number of Displaced Physicians.**—Provisions for placement of a limited number of displaced physicians in North Dakota were made in Grand Forks January 8 by Dr. Olafur W. Johnson, Rugby, president of the North Dakota State Board of Medical Examiners. Dr. Johnson said that displaced physicians not to exceed eight per year for three consecutive years would be permitted to take the State Board Examinations for a temporary license after first serving a general internship for one year in North Dakota hospitals approved for that purpose. Dr. Johnson pointed out that inasmuch as the accredited social agencies which sponsor displaced persons are responsible for them until they have attained citizenship, the temporary licenses will be valid only in the community where the displaced physician has been located by the sponsoring agency. "When the displaced physician is granted his final citizenship," said Dr. Johnson, "he will be granted full license on review by the State Medical Board. In the case of these displaced physicians no records of medical education, medical attainment or credentials are available to help the board in their determination. The board nevertheless feels that as much as possible should be done to help out the worthy among these unfortunate persons. We think that with the supervision now provided the people in North Dakota may be safely protected, and the year's internship will provide a period of adjustment during which the displaced physician may learn the English language, American customs and refresh himself in the advancement in medical science as practiced in the United States."

## OHIO

**Dr. Upham Made Emeritus Member of Board.**—Dr. John H. J. Upham, Columbus, who served thirty-five years as a member of the Ohio State Medical Board, was named an emeritus member in December. Dr. Upham's fifth term expired in March 1948. Dr. Paul H. Charlton, Columbus, has been appointed to succeed him as active member. Dr. Charlton is an associate professor of surgery at the Ohio State University College of Medicine and a former president of the American Medical Association.

**Regional Blood Center at Columbus.**—The Columbus Regional Blood Center of the American Red Cross was opened December 7 at 30 East Town Street, the eighteenth center to be opened in the nation. It is fully equipped with laboratories in which the blood is tested, typed, processed and refrigerated. A bloodmobile unit staffed with a doctor and six nurses has started regular scheduled visits to towns in twenty counties in central Ohio. It is anticipated that thirty counties will participate in the program. Dr. John W. DeVore is physician-technical director of the center, which is staffed with twelve registered nurses, four medical technologists and three blood custodians.

## OKLAHOMA

**First Taylor Lecture.**—Dr. Herman L. Kretschmer, clinical professior of urology, University of Illinois College of Medicine, Chicago, delivered the first annual Charles B. Taylor Lecture on January 11, at the University of Oklahoma School of Medicine, Oklahoma City. This lectureship was established by Mrs. Sarah Edwards of Oklahoma City in memory of her late husband, Mr. R. J. Edwards, and honoring Dr. Charles B. Taylor, professor emeritus of urology of the school of medicine, where he has been a member of the faculty for the past twenty-eight years.

## TEXAS

**Crippled Children's Emergency Fund.**—El Katif Shrine of Galveston has established a Shriner Crippled Children's Emergency Fund at the University of Texas Medical Branch, Galveston, with a donation of $1,000. Established by a Negro organization, the fund is to be used for the benefit of crippled children without regard to race or religion. The fund will be administered by Dr. Arild E. Hansen, professor of pediatrics and director of the Child Health Program at the university.

**Fund Established at University.**—The H. H. Weinert Endowment Fund for Cardiovascular Research has been established at the University of Texas Medical Branch, Galveston, by members of the family of Mr. H. H. Weinert of Seguin, a former regent of the university. The endowment is for supporting the researches of Dr. George R. Herrmann, professor of medicine and director of the Cardiovascular Research Laboratory, on factors in the cause and control of arteriosclerosis. Contributions to the fund to date total more than $15,000.

**Annual Dallas Spring Clinical Conference.**—The Dallas Southern Clinical Society will hold its eighteenth annual Spring Clinical Conference March 15-17 with headquarters at the Hotel Adolphus and Baker Hotel, Dallas. Guest speakers will be presented in general assemblies, afternoon clinics, round table luncheon conferences, afternoon and evening symposiums and a clinical pathologic conference. The program is as follows:

Elexious T. Bell, Minneapolis, Primary Hypertension, Especially with Reference to Changes in the Kidneys.
A. Benson Cannon, New York, Treatment of Common Skin Diseases.
Richard B. Cattell, Boston, Management of Hyperthyroidism.
Lowell S. Goin, Los Angeles, Management of Leukemia.
T. Campbell Goodwin, Cooperstown, N. Y., Prevention and Treatment of Tuberculosis.
A. McGehee Harvey, Baltimore, Recent Advances in Medical Therapy.
Francis L. Lederer, Chicago, The Otolaryngologist Looks at the Tonsil Problem.
Robert M. McIver, Jacksonville, Fla., Backache—A Urologist's Viewpoint.
Julian M. Ruffin, Durham, N. C., Modern Management of Peptic Ulcer.
Herbert E. Schmitz, Chicago, Prolonged Labor.
Kenneth C. Swan, Portland, Ore., Contemporary Concepts of Corneal and Scleral Processes.
Nathan A. Womack, Iowa City, Diagnosis of Diseases of the Liver.

A registration fee of $20 covers all lectures, luncheons and the annual banquet.

## VIRGINIA

**Personal.**—Dr. Oscar R. Yates, Suffolk, was presented the annual Silver Beaver Award in December by the Old Dominion Area Council of Boy Scouts. He has served as chairman of the council health and safety committee and has participated in scouting for the last twenty years.

**Appoint Professor of Medicine.**—Dr. William Parson, former instructor in medicine at Tulane University of Louisiana School of Medicine, New Orleans, has been appointed professor of medicine at the University of Virginia Department of Medicine, Charlottesville, effective July 1. Dr. Parson is a graduate of Columbia University College of Physicians and Surgeons, New York, 1937, and was a research fellow at Johns Hopkins University in 1942 before being associated with Tulane University.

## WASHINGTON

**Plague-Infected Fleas.**—Under date of November 29, according to the U. S. Public Health Service, plague infection was reported proved in a pool of 43 fleas from 11 short-tailed meadow mice, Lagurus curtatus, trapped November 4 on the Bickelton road 16 miles southwest of Mabton, Yakima County, and in a pool of 88 fleas from 60 white-footed mice, Peromyscus maniculatus, trapped on the same date in the same locality.

## WEST VIRGINIA

**License Revoked.**—The Public Health Council has revoked the license of Dr. Jerome H. Toupkin of Whitesville to practice medicine in West Virginia because of his conviction on a felony charge.

**Submit Bill for Health Department Reorganization.**—A proposed bill for reorganization of the West Virginia Department of Health was approved at a recent meeting of the Council of the West Virginia State Medical Association meeting January 8. It provides for a state board of health to be composed of three physicians or surgeons, one dentist, one osteopathic physician, one pharmacist, one hospital representative and two representative citizens. The members would be appointed for staggered terms of one to nine years. Not more than five of the nine members could belong to the same political party. Not less than one or more than two members could be appointed from the same congressional district. The board would have powers similar to those now vested in the board of governors of West Virginia University, and would have supervision and control of the hospital proposed to be built in connection with the four year school of medicine and dentistry. The bill would provide for the biennial registration of doctors in accordance with the plan heretofore approved by the council. A medical licensing board to handle all matters relating to licensure to practice medicine in West Virginia would take the place of the present Public Health Council. Under the proposed bill, all state tuberculosis, mental and general hospitals, with the exception of the hospital planned in connection with the medical-dental school, would remain under the supervision of the board of control. The crippled children's division would remain in the department of public assistance.

## WISCONSIN

**Dr. Waters Retires.**—Dr. Ralph M. Waters voluntarily retired as professor of anesthesia in the University of Wisconsin Medical School January 1. Dr. Waters came to the university in 1926. In 1944 he was awarded the Hickman Medal by the Royal Society of Medicine of London, and in 1947 the King of Sweden conferred on him the Order of Vasa for training Swedish doctors at the Wisconsin General Hospital. In 1946 he was awarded the Cutter Medal of the Phi Rho Sigma Fraternity, and he was the first recipient of the Distinguished Service Award by the American Society of Anesthesia.

**Appointments to Marquette.**—Dr. Edward A. Bachhuber has been appointed assistant dean of Marquette University School of Medicine, Milwaukee. He will be in charge of the medical educational program for medical students and residents at the Milwaukee County institutions. The appointment follows a recently arranged affiliation between the Marquette University School of Medicine and the county institutions. Dr. F. Herbert Haessler has been appointed to a full time professorship in ophthalmology at the university. He is a graduate of Johns Hopkins University School of Medicine, Baltimore, 1916. The professorship has been established in memory of the late Dr. John L. Yates and his sister Carol M. Alice. Dr. Haessler will develop a graduate training program in ophthalmology.

## GENERAL

**National Cancer Control Month.**—The American Cancer Society will conduct its annual drive in April, which is to be "National Cancer Control Month." The society will seek $14,500,000 as the minimum goal. Charles F. Kettering, industrialist, who became cosponsor of the Sloan-Kettering Institute for Cancer Research, will direct the campaign.

**Scholarship in Lip Reading.**—A $100 scholarship is being offered in 1949 by the American Hearing Society, trustee of the Kenfield Memorial Fund. Applications will be considered from any prospective hard of hearing teacher of lip reading to hard of hearing adults who lives in the United States and who can meet the necessary requirements of education and experience. Applications from those who are teaching lip reading now cannot be considered. Applications must be filed between March 1 and May 1 with Miss Rose V. Feilbach, Teachers Committee, 817 14th Street, N.W., Washington 5, D. C.

**Prize for Essay on Thyroid Problems.**—The American Goiter Association again offers the Van Meter Prize Award of $300 for the best essay submitted concerning original work on problems related to the thyroid gland. The award will be made at the annual meeting of the association in Madison, Wis., May 26-28, providing essays of sufficient merit are presented in competition. The essays may cover either clinical or research investigations, should not exceed 3,000 words, and must be presented in English not later than March 15. Typewritten, double-spaced copy should be sent to the corresponding secretary, Dr. T. C. Davison, 207 Doctors Building, Atlanta 3, Georgia.

**Dr. Ferree Appointed to American Heart Association.**—Dr. John W. Ferree, New York, has been named director of the Public Health Division of the American Heart Association. He will direct the development of public health programs for the association and will assist local groups in expanding and maintaining effective cardiac services in communities throughout the United States. During the last two years Dr. Ferree has been executive director of the National Health Council in New York and, earlier, director of Educational Services for the American Social Hygiene Association. He is a graduate of the Indiana University School of Medicine, 1932, and from 1940 to 1942 was state health commissioner of Indiana. During the war he served as commander in charge of the Venereal Disease Section, Division of Preventive Medicine, Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

**National Research Council Enters Fight Against Alcoholism.**—At a special meeting the Research Council on Problems of Alcohol voted to turn over its research operations and assets to the National Research Council of Washington, D. C. It was also voted that the public informational and educational publications be turned over to the Division of Mental Hygiene, U. S. Public Health Service. Both national organizations have agreed to accept the pertinent assets and carry on the work of the council. During the past eleven years the Research Council on Problems of Alcohol, whose activities are now completed, has spearheaded in medical schools and other scientific institutions investigations into the causes and treatment of problem drinking. Under its leadership a number of state governments and communities have established medical care programs for problem drinkers. For the past several years Dr. Anton J. Carlson, Chicago, has been its president and scientific director.

**Research Needs in Rheumatic Diseases.**—The National Research Council Committee, appointed to survey research needs in rheumatic diseases, recently reported to the Arthritis and Rheumatism Foundation the need of at least $6,100,000 for research alone over the next five years. According to the report, about 7,500,000 Americans have arthritis or some other form of rheumatic disease. Seventeen physicians and scientists under the chairmanship of Dr. Walter Bauer of the Harvard Medical School, Boston, participated in the survey report. The five year program they recommended calls for $4,300,000 for the support of researches and $1,800,000 in research fellowships to train young investigators. The committee also recommended the following: research on "embryonic mesenchymal tissue"; specific clinical and physiologic problems of arthritis and rheumatic diseases as well as social, environmental and other public health factors bearing on them; the relation of germ and virus infection to the onset of rheumatoid arthritis and of rheumatic fever; studies of the blood and circulatory system aimed at checking osteoarthritis; hereditary factors in relation to these diseases, and emotional factors related to the development and persistence of arthritis. The Arthritis and Rheumatism Foundation, for which the report was prepared, has its offices at 535 Fifth Avenue, New York City, and is now trying to raise $2,000,000 for its first year program. Half of this money is to be devoted primarily to research, and the other half is being sought for local programs for better care and training.

**Scientific Assembly of Academy of General Practice.**—The first annual scientific assembly of the American Academy of General Practice will be held in Cincinnati at the Netherlands Plaza Hotel March 7-9, under the presidency of Dr. Paul A. Davis, Akron, Ohio. The program is as follows:

Walter C. Alvarez, Rochester, Minn., The Patient Who Is Always Tired and Nervous.
M. Edward Davis, Chicago, Management of the Placental Stage in the Prevention of Postpartum Hemorrhage.
John E. Dees, Durham, N. C., Bladder Irritation in the Female.
Charles A. Doan, Columbus, Ohio, Hypersplenic Syndromes: Their Recognition and Management.
Joseph A. Freiberg, Cincinnati, Some Facets of Low Back Pain.
Lowell S. Goin, Los Angeles, The General Practitioner and the Radiologist as a Cancer Finding Team.
Francis C. Grant, Philadelphia, Surgical Methods for the Relief of Intractable Pain.
Tinsley R. Harrison, Dallas, Texas, Types and Causes of Heart Failure.
Robert A. Kehoe, Cincinnati, General Medical Practice in Relation to Industrial Medicine.
John A. Kolmer, Philadelphia, Practical Applications of Synergistic and Additive Chemotherapy.
Karl A. Meyer, Chicago, Surgical Management of Massive Intestinal Hemorrhage.
Norman F. Miller, Ann Arbor, Mich., The Human Cervix in Health and Disease.
Francis D. Murphy, Milwaukee, So-Called Malignant Hypertension.
Franklin D. Murphy, Kansas City, The Medical School and Rural Health.
Walter J. Reich, Chicago, Practical Office Procedure in Gynecology.
Howard A. Rusk, New York, Role of the General Practitioner in Rehabilitation of the Patient with Chronic Disease.
Tom D. Spies, Birmingham, Ala., Vitamins in the Practice of Medicine.
Philip Thorek, Chicago, Intestinal Obstruction.
Herman G. Weiskotten, Syracuse, Medical Education and Its Relation to General Practice.
Paul A. Davis, Akron, Pitfalls in Occupational Disease Diagnosis to Be Avoided by the General Practitioner.

A guest registration fee of $5 will be charged. Officers to be installed at the close of the assembly are Elmer C. Texter, Detroit, president; Stanley R. Truman, Oakland, Calif., president elect; Jason P. Sanders, Shreveport, La., vice president; Mr. Mac F. Cahal, Kansas City, executive secretary, and Ulrich R. Bryner, Salt Lake City, treasurer.

## FOREIGN

**United Nations Nutritional Survey.**—The need for outside nutritional help and relief in six European countries is more acute than a year or two ago, according to a report compiled by Dr. Henry F. Helmholz, Rochester, Minn., and Johann Latsky for the International Children's Emergency Fund. The report covers a six month investigation of conditions in Austria, Czechoslovakia, Greece, Hungary, Italy and Rumania. In none of these countries, the report states, was the condition of the child population satisfactory. Conditions are attributed to three causes: lack of safe-quality domestic milk supplies; slaughter of dairy herds and the failure of food and animal-feeding crops as a result of previous droughts. All six countries are below recommended standards for adequate nutrition, and there is a general chronic shortage of foods of animal origin.

## LATIN AMERICA

**Latin American Medical Society.**—The Sociedade Paraense de Ginecologia e Obstetricia was established in Belem and Para cities, Brazil, on May 8, 1948, with temporary headquarters at the faculty of medicine of Belem. Dr. Orlando Bordallo, Belem, is the president of the society.

---

# Marriages

Stanley A. Skillicorn, San Jose, Calif., to Miss Joan Patton of Long Beach, in Gilroy, recently.

Charles A. Jarvis, Ilion, N. Y., to Miss Louise Marie Wilson of Crescent City, Fla., in October.

Hiram Wilson Davis, Richmond, Va., to Miss Shirley Powers Davis of Atlanta, in November.

Eugene A. White, Boston, to Miss Virginia Holmes of Cambridge, N. Y., November 20.

Abraham Irving Friedman to Miss Helene Marion Bennett, both of New York, July 29.

Bruce R. Marshall, Bedford, Ohio, to Miss Florence Pope in Youngstown, October 14.

# Deaths

**William Coughlin Braislin,** New Canaan, Conn.; born in Burlington, N. J., in 1865; College of Physicians and Surgeons, medical department of Columbia College, New York, 1890; formerly on the faculty of the Long Island College of Medicine; specialist certified by the American Board of Otolaryngology; member of the American Medical Association, Medical Society of the State of New York, American Laryngological, Rhinological and Otological Society and the American Otological Society; fellow of the American College of Surgeons; on the advisory board of the Selective Service during World War I; for many years affiliated with the Brooklyn Eye and Ear Hospital; died in the Norwalk (Conn.) Hospital December 2, aged 83.

**Eugene Vernon Powell,** Waco, Texas; born in Galveston, Aug. 2, 1891; University of Texas School of Medicine, Galveston, 1914; member of the American Medical Association and the American Roentgen Ray Society; a charter member and past president of the Texas Radiological Society; past president of the Bell County Medical Society; specialist certified by the American Board of Radiology; at various times associated with Mount Sinai Hospital in New York, King's Daughters Hospital in Temple, Terrell Clinic, Fort Worth, Hillcrest and Providence hospitals in Waco; affiliated with the Veterans Administration Hospital; died October 18, aged 57, of coronary occlusion.

**John Milton Acton,** Danville, Ky.; Kentucky School of Medicine, Louisville, 1898; served during World War I; formerly health officer of Boyle and Garrard counties; on the staff of the Ephraim McDowell Hospital; died November 20, aged 72, of arteriosclerosis.

**Paul Allen,** Montclair, N. J.; New York Homeopathic Medical College and Hospital, New York, 1889; formerly on the faculty of his alma mater; died November 20, aged 85.

**Walter Garvin Aughenbaugh** ⊕ Pittsburgh; University of Pittsburgh School of Medicine, 1913; affiliated with St. John's General Hospital, where he died November 23, aged 59, of coronary occlusion.

**Wendell Lee Ball** ⊕ Pacific Grove, Calif.; University of Oregon Medical School, Portland, 1938; served during World War II; died November 14, aged 36.

**Moses Burette Barber,** Fredericktown, Mo.; Barnes Medical College, St. Louis, 1899; member of the American Medical Association; died in Ironton November 7, aged 79, of injuries received in an automobile accident.

**Horace Cleveland Bare** ⊕ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1901; on the courtesy staff of the Lankenau Hospital; died November 18, aged 70, of cerebral thrombosis.

**Alcimus H. Baskin,** Atlanta; Atlanta Medical College, 1892; formerly city councilman and police commissioner; died November 17, aged 79.

**Thaddeus Park Bell,** New Orleans; University of the South Medical Department, Sewanee, Tenn., 1900; died in Baptist Hospital November 24, aged 73, of coronary thrombosis with infarction.

**Charles Herbert Benson,** Bainbridge, N. Y.; Syracuse University College of Medicine, 1891; at one time medical superintendent of the Syracuse (N. Y.) Free Dispensary Service; died November 28, aged 83, of myocarditis, uremia and hypertrophy of the prostate.

**Russell Eldridge Blankinship Jr.,** Lynchburg, Va.; University of Virginia Department of Medicine, Charlottesville, 1948; served during World War II; intern at the U. S. Marine Hospital in Staten Island, N. Y., where he died November 28, aged 25.

**George Boody Sr.,** St. Paul; Northwestern University Medical School, Chicago, 1891; died November 11, aged 82.

**Oscar Daniel Brock,** London, Ky.; University of Louisville (Ky.) Medical Department, 1911; member of the American Medical Association; for many years mayor; died in the Marymount Hospital November 15, aged 65, of injuries received in an automobile accident.

**Erie Newell Brown,** Marengo, Iowa; State University of Iowa College of Medicine, Iowa City, 1888; served as health officer, president of the school board and on the board of the public library; died November 25, aged 85, of left ventricular cardiac failure.

**Sara Winifred Brown,** Washington, D. C.; Howard University College of Medicine, Washington, 1904; a trustee of Howard University; died November 12, aged 80, of a skull fracture received when struck by a bus.

**Samuel Collins Buchan,** Chicago; Bellevue Hospital Medical College, New York, 1877; died November 27, aged 97, of cerebral hemorrhage.

**Richard Lawrence Campbell** ⊕ East St. Louis, Ill.; Washington University School of Medicine, St. Louis, 1900; past president of the board of education and of the St. Clair County Medical Society; affiliated with St. Mary's Hospital, where he died November 24, aged 80, of carcinoma of the stomach.

**Arthur Clinton Carter,** South Dartmouth, Mass.; Tufts College Medical School, Boston, 1936; member of the American Medical Association; served as school physician; on the staffs of Sassaquin Sanatorium and St. Luke's Hospital in New Bedford, where he died November 26, aged 48, of coronary thrombosis.

**Michael Gregory Chadman** ⊕ Lancaster, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1921; certified by the National Board of Medical Examiners; for many years affiliated with St. Joseph's Hospital; died November 15, aged 51, of coronary occlusion.

**Theodore Charles Fegley** ⊕ Tremont, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; served during World War I; for many years county coroner; affiliated with Pottsville (Pa.) Hospital; died November 17, aged 72, of coronary thrombosis.

**Romeo Catlin Harner,** Howard, Kan.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; member of the American Medical Association; died November 4, aged 80.

**William J. Hatfield,** Topeka, Kan.; Medical College of Indiana, Indianapolis, 1890; member of the American Medical Association; died recently, aged 81, of cerebral hemorrhage.

**Earl Frederick Jamieson,** Brainerd, Minn.; College of Physicians and Surgeons, Boston, 1911; member of the American Medical Association; affiliated with St. Joseph's Hospital; died October 19, aged 61, of coronary occlusion.

**John Fletcher Lunsford,** Preston, Ga.; University of Georgia Medical Department, Augusta, 1901; member of the American Medical Association; affiliated with the Americus and Sumter County Hospital in Americus, where he died October 22, aged 71, of hypertensive cardiovascular disease.

**Donnell M. Pearson,** Louisiana, Mo.; Washington University School of Medicine, St. Louis, 1891; member of the American Medical Association; affiliated with Pike County Hospital; died October 12, aged 77, of coronary thrombosis.

**Charles D. Pettigrew,** Muncie, Ind.; Medical College of Indiana, Indianapolis, 1898; died October 27, aged 72, of coronary thrombosis.

**Louis De Laittre Pulsifer,** Mexico, N. Y.; Syracuse University College of Medicine, 1900; member of the American Medical Association; served on the school board, as health officer and as mayor; during World War II a member and medical examiner of the local draft board located at Pulaski; died October 26, aged 76, of coronary thrombosis and arteriosclerosis.

**Ernest B. Scholten** ⊕ Reading, Pa.; Christian-Albrechts-Universität Medizinische Fakultät, Kiel, Prussia, Germany, 1893; died in the Reading Hospital October 7, aged 81, of carcinoma of the rectum.

**Lawrence Simcox** ⊕ Gulfport, Fla.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; died October 3, aged 78, of coronary occlusion.

**William Franklin Smith,** Chadbourn, N. C.; North Carolina Medical College, Davidson, 1904; member of the American Medical Association; served as chairman of the local school board; died November 11, aged 72, of heart disease.

**Wilfred Mark St. Georges,** Holyoke, Mass.; Baltimore University School of Medicine, 1893; retired school physician; served during World War I; affiliated with Holyoke City Hospital and Providence Hospital, where he died November 6, aged 77, of hypertrophy of the prostate with obstruction.

**William Norbury Vreeland,** Plainfield, N. J.; Columbia University College of Physicians and Surgeons, New York, 1901; served on the staff of the Fairmount Hospital in Jersey City; died in Muhlenberg Hospital, November 7, aged 71, of a ruptured abdominal aneurysm.

**Arthur Wellesley Wood,** Miami, Fla.; Atlanta School of Medicine, 1910; member of the American Medical Association; died November 21, aged 63, of acute coronary thrombosis.

**Gautier Conde Yancey,** Tuskegee, Ala.; University of Alabama School of Medicine, University, 1919; member of the American Medical Association; died November 14, aged 54, of cirrhosis of the liver.

### The Hospitals Under the National Health Service

All the hospitals of the country, with some unimportant exceptions, have been taken over by the government under the National Health Service scheme. A report of the first half-year's work under the new system has been issued by the South West Metropolitan Regional Hospitals Board, which took over more than five hundred hospitals containing 68,000 beds. The board found that the transfer was smoother than was expected and claims that the services have already been improved in some respects. But there is a critical situation due to shortage of staff accommodation of every description and the public now tends to expect beds on demand in return for the compulsory contribution. The board has made contracts with 950 part time and 350 whole time specialists. Facing the shortage of specialists, which is not expected to be overcome in less than fifteen years, the Board hopes to gain by converting some part time into whole time specialists. The ultimate aim is that every patient will be in the charge of a specialist. Difficulties over lower medical appointments are likely to decrease through deferment of military service.

The mental service in the region has an equally difficult task. To remedy a shortage of psychiatrists the board has introduced a training scheme under which they will go through the hospital in a course lasting two years. Overcrowding of patients is partly due to the fact that medical superintendents of mental hospitals had no power to refuse cases. The special nature of the problem has been recognized by the board's giving each of the twenty-three mental hospitals its own management committee and decentralizing work as much as possible. The whole service still remains under the control of voluntary workers, and members of the original board still hold honorary appointments. This point is made for the assurance of the public that the hospitals have not passed under complete bureaucratic control. This gradualness and desire to hold on to the advantages of the past system of management by voluntary workers is characteristically English. Such a socialistic revolution in other countries probably would mean a complete break with the past.

### The Australian Government Defies the British Medical Association

The failure of the Australian Government to introduce a National Health Service, in consequence of the resistance of the British Medical Association, has been reported in previous letters to The Journal. But the government persists in its intention. The Minister of Health, Senator McKenna, has written to the president of the federal council of the association, stating that the government intends to put its scheme into operation within the limits of its constitutional power and not to alter its proposals on the points in dispute with the British Medical Association. He said that the government had exhausted every effort to obtain the cooperation of the British Medical Association, and that it did not intend its proposals to be further delayed or frustrated by the association. He rejected as without foundation suggestions that a national health service would involve government control of every aspect of medical practice. This may be true but does not exclude much control that the medical profession considers detrimental to the practice of medicine, as has occurred in Britain.

### The Prevalence of Tuberculosis

The Royal College of Physicians has published one of the most comprehensive investigations into the development and prevention of tuberculosis in young adults ever made. The disease accounts for more deaths between the ages of 15 and 24 in England and Wales than any other malady and for about half the deaths caused by all the diseases. The danger of exposure to infection in young adults is greater than is generally realized. Young women are more likely to suffer than young men, and the risk is more or less in proportion to the degree of exposure to infection. Measures recommended included the bringing under treatment as early as possible, provision of safe employment for chronic infective patients, mass roentgenography to discover unsuspected cases and freeing milk from the danger of spreading tuberculosis.

The National Association for the Prevention of Tuberculosis has also just issued its annual report, which shows that of 2,000,000 persons examined by mass roentgenography in the past year 95 per cent had normal chests. Only 4 per thousand had active pulmonary tuberculosis. One per thousand had bronchiectasis. The report suggests that each regional hospital board should have a permanent committee and a doctor of high clinical and administrative ability to coordinate a complete service for tuberculosis and chest diseases. Both reports complain of the long waiting lists for admission to sanatoriums and the consequent delay in admission.

### A Science Center To Be Established

The president of the Royal Society, Sir Robert Robinson, at the two hundred and eighty-sixth anniversary meeting, referred to the need for adequate accommodation for scientific societies and announced that it had been unanimously agreed that the institution of a scientific center would provide the best solution. The Royal Society could function as its heart. One of the schemes that had been approved by the Rutherford Memorial provided for a "Rutherford Hall" of noble design.

*The Soviet Persecution of Russian Biologists.*—The president then referred to an incident that "has rudely disturbed our peace of mind"—the report that eminent Russian biologists had been constrained to subscribe to interpretations of the data in the field of genetics which they had previously rejected. According to *Pravda*, "The Academy of Sciences forgot that the most important principle in science is the party principle." The society regretted that the Academy of Sciences of Moscow has broken off its long correspondence with them. The new conditions, it is hoped, will not seriously impede the advance of biologic science, for which such qualifications as "western" are as irrelevant as they would be for the multiplication table. No such direct attack on the freedom of science is likely to occur here. But conceivably it might take the more subtle form of control of the character and direction of our scientific work. There is immediate danger in the current depreciation of fundamental research, not of course absolutely, but relatively, in comparison with technologic applications. The president expressed hope that it would be the opinion of all the fellows that the Royal Society should take a leading part in upholding their ideals and in insisting on the role which the highest kind of disinterested investigation must play in the life of the community.

### Ophthalmologic Congress

The annual congress of the Ophthalmological Society will be held in London March 31-April 2. The subject for discussion will be Corneal Grafting. The opening speakers will be Dr. R. Townley Paton, New York; Prof. A. Franceschetti, Geneva; Prof. G. P. Sourdille, Nantes, and Mr. J. W. Tudor, Cardiff. Further particulars may be had from the hon. secretaries, 45 Lincoln's Inn Fields, London, W. C. 2.

### Congress of Obstetrics and Gynecology

The twelfth British Congress of Obstetrics and Gynecology will be held in London July 6-8, under the presidency of Sir Eardley Holland. The subjects for discussion include "Modern Caesarean Section," Dr. C. McIntosh Marshall; "Essential Hypertension in Pregnancy," Prof. G. W. Pickering and Prof.

F. J. Browne; "Modern Concepts in the Diagnosis, Treatment and Prognosis of Carcinoma of the Uterus," Dr. J. E. Ayre, Montreal, Prof. G. Strachan, A. Glucksmann and Dr. Joe Meigs, Boston, and "Maternal Mortality," Sir William Gilliatt. Further information may be had from Dr. A. J. Wrigley, hon. secretary, 58 Queen Anne St., London, W. 1.

## ITALY

*(From Our Regular Correspondent)*

FLORENCE, Dec. 15, 1948.

### National Congress of Internal Medicine

The Italian Association of Internal Medicine held its forty-ninth congress in Bologna October 18-21, contemporaneously with the congress of the Surgical Association.

Reports on the first subject, "Visceral Pain," were presented jointly with the Surgical Association and the Italian Obstetrical and Gynecologic Association.

Professor Lunedei, University of Florence, the speaker from the medical point of view, discussed the principles of the physiopathology of pain.

Professor Comolli, one of the speakers from the surgical point of view, analyzed abdominal pain, considering the pathways of transmission of pain in the various serous and visceral formations. Professor Mangione, the second speaker from the surgical point of view, analyzed the character of the elementary visceral pain of the esophagus, of the stomach and of the various enteric segments; he particularly considered surgical intervention as antalgic treatment of great actuality in the treatment of pain.

Professor Paroli, speaker from the obstetricogynecologic point of view, discussed the pathways of transmission of algogenic impulses of the female genitals and the neuromeric connections of the genital sphere.

A discussion followed the reports in which, among others, Professor Gasbarrini, medical clinic of the University of Bologna, participated.

For the second subject reported on, "The Pathology and Symptomatology of Hemoplasmopathies," the speaker was Professor Poli. He recalled that today the hemoplasmopathies represent a new phase in the study of the many disease processes which have their fundamental substrate in the changes of the protein constituents of the blood plasma. One has to deal with a peculiar localized disturbance in the liquid interstice of the blood, to which functions of highly vital importance are assigned normally. The occurrence of abnormal proteins in the blood serum presents one of the fundamentals of the general pathology of the hemoplasmopathies; it may be revealed by the study of the behavior of the crystalline precipitation, by the reaction to heat, by biologic variations and those of immunity and by the clinical constitution. Variations of the protein spectrum are of considerable importance, and so are the tests of colloidal lability, actually in use in the laboratory. In the problem of the plasmopathic disturbances, the speaker emphasized that an activation of the reticuloendothelial system associated with an increase in plasma cells may be considered always as the basis of those disorders. One may observe an increase in globulin among the protein fractions. The alterations of the proteinemic picture involve a modification of the functions transferred to the proteins, of the transport of some of the substances and of the maintenance of the oncotic pressure. There are also variations in the coagulation of the blood and sero-immune reactions. The elimination of the abnormal proteins from the excretory organs and the accumulation of proteins in proximity to plasmacellular proliferation are the direct consequences of these pathologic states.

Clinically, the hemoplasmopathies may be divided in primary, typical secondary and minor. One group of hemoplasmopathies has regard to the arthropathies and hepatopathies. Measles, leishmaniasis and sarcoidosis belong to the plasmopathies of secondary type. Among the minor forms there are the acute and chronic infectious diseases, acute articular rheumatism, some deficiency plasmopathies, some neoplasias, some endocrinopathies and hemopathies. On the basis of anatomic-pathologic and clinical studies the speaker sketched a new pathogenic concept of nephrosis, which he considers a true and peculiar primary hemoplasmopathy.

In his conclusions Professor Poli stated that the present systematization of the hemoplasmopathies must be considered as provisional and is definitely bound to undergo many changes. It nevertheless represents a useful plan for connecting various morbid processes which so far have not been tied together, and to which only clinical experience and profound biochemical research may give a definite orientation.

The third subject reported on was "Cephaleas." A report was presented by Professor Greppi, clinical physician of the University of Florence, who recalled the chief algogenic zones of the cephalic region and of the endocranium. He then discussed the play of the physico-chemico-humoral mechanisms which regulate the cerebral circulation, dwelling particularly on the cephalea from histamine, which serves as a basic test for many forms of cephalea, because the intensity of the phenomena released by histamine is such that it may be regulated exactly on a sensibility threshold.

## AUSTRALIA

*(From Our Own Correspondent)*

Jan. 4, 1949.

### National Health Service Act, 1948

The year 1949 promises to be vital for the future of medical practice in Australia. The government, when it was elected to power three years ago, promised to introduce a national medical scheme. The government's term ends this year, and the inception of a plan is a political necessity.

It will be remembered that the government introduced a "free medicine" plan last July, but over a period of six months, instead of between 10,000,000 and 20,000,000 free prescriptions being dispensed as was expected, only 20,000 were tendered in accordance with the formulary. This situation was due to two factors, opposition by the well organized profession and apathy on the part of the public.

Free medicine, then, having been a failure, the Health Minister, Senator McKenna, introduced into parliament November 28 the National Health Service Act 1948, the outstanding feature being the payment of half the doctor's fee. The amount would be paid direct to the doctor in accordance with a "prescribed schedule of fees chargeable by doctors who participate." This plan would also apply to dentists. Estimated yearly cost was £6,000,000 for medical benefit and £4,000,000 for dental.

The bill was only an enabling measure, giving power to begin such a scheme and "leaving details of the service and its administration to progressive development by regulations." The government did not contemplate, nor did the constitution permit, any nationalization of doctors, dentists or allied professions.

The bill enables the commonwealth to provide or arrange for medical and dental services, including general practitioners' service, consultant and specialist services, ophthalmic services, maternal and child health services, convalescent, after-care and nursing services and medical and dental services in universities, schools and colleges; establish and maintain hospitals, laboratories, health centers and clinics; make payments to assist research and provide training courses in medical or dental science; provide or assist in the provision of postgraduate training and scholarships in medicine and dentistry; establish and develop courses of training in nursing, dental hygiene, radi-

# Medical Motion Pictures

## FILM REVIEW

**A Day in the Life of a Cerebral Palsied Child.** 16 mm., color, sound, 875 feet (1 reel), showing time thirty minutes. Prepared in 1948 under the supervision of Dr. Winthrop M. Phelps, Director, The Children's Rehabilitation Institute, Cockeysville, Md. Produced by Hudson Production, Los Angeles. Sponsored by and procurable on loan or purchase from The Information Services of the National Society for Crippled Children and Adults, 11 South LaSalle Street, Chicago 3.

This motion picture depicts the activities and problems of a boy with cerebral palsy. He is followed from his awakening in the morning through the day's work and play. Since the scene is laid in an institution for children with this affliction, many other cases are seen incidentally, and they exhibit various forms of the condition and various degrees of severity. The problems of dressing, eating, standing, walking, talking, writing, and undressing are taken up in turn. The film has an emotional impact as a result of the watching of the extraordinary amount of help required by the victims by their courage and by the resourcefulness of their attendants. It raises the hope that means for preventing this distressing disorder may soon be found. Emphasis is placed on the application of the methods of physical medicine and occupational therapy in cerebral palsy. It suggests, but does not answer, the question as to how much is accomplished by some of these methods. If money can be made available, something valuable could be learned by retaking pictures of these same children during at least the next five years. A better understanding of cerebral palsy by the public at large should lead to a concerted effort not only to aid present victims but to find means of prevention, and this film should contribute notably toward this end. In the beginning of the film it might have been better to utilize the footage by demonstrating examples of the cases discussed by the lecturer.

The film would be valuable for showing to physical therapists and occupational therapists, to physicians who deal with such children in private practice and corrective physical education personnel. It will also be useful in rousing medical students and nurses to a sense of the importance of this condition, which can not be appreciated simply on seeing such patients in clinics. If the technical terms were given further explanation, the film would have real value for parents of cerebral palsied children as well as lay groups interested in the welfare of such children. The photography and narration are excellent.

# Bureau of Legal Medicine and Legislation

## MEDICOLEGAL ABSTRACTS

**Workmen's Compensation Acts: Death of Employee During Company Sponsored Baseball Game.**—The plaintiff filed a claim for a compensation award by reason of the death of her husband during the course of his employment with the Crosley Corporation. A judgment of the trial court reversed an opinion of the Industrial Commission and allowed an award so the defendant appealed to the court of appeals of Ohio, Hamilton County.

The deceased was an employee of the Crosley Corporation and performed the duties of a guard. The corporation had adopted a recreation program for its employees in which provision was made for the playing of baseball games. Playing equipment was furnished by the corporation and the program was directed by a paid supervisor, who made arrangements for the forming of several teams of corporation employees, made the schedule of games and selected sites for playing. The players wore shirts prominently displaying the name of the corporation or enough thereof to identify them as Crosley employees. When the notice for enrolment of players was first posted, the deceased had sought to join one of the regular teams, but was dissuaded from doing so because he was older than the players composing the teams and also because his work as a guard interfered with the time schedule of the games. The deceased then formed a team of "Crosley Guards," so designated on the shirts worn by the players in his team. This was sufficient to identify the players as employees of the corporation, and spectators of the games knew that the players were all Crosley employees. The "Crosley Guards" were not entered in the main schedule of teams and were not a part of the regular league of Crosley teams, but they were furnished playing equipment by the corporation. There was no question but that their activity was sponsored by the corporation and was in the general purview of the recreational program for employees of the corporation, designed to promote the health and the general welfare of the participants, cultivate a friendly relationship with the corporation and incidentally advertise its existence to the public. During the last game in which the deceased played, he was running the bases when he was tagged out. He walked to the players' bench and, on being seated, immediately fell dead.

In 1929, the Industrial Commission, in view of the fact that so many employers encouraged their employees to engage in athletics, sometimes during and sometimes outside working hours, adopted the following resolution:

> Be it therefore resolved by the Industrial Commission of Ohio, that in all cases where the employer encourages the employees to engage in athletics, either during working hours, or outside of working hours, and supervises and directs, either directly or indirectly, such activities, meritorious claims for injuries to any such employees while so engaged will be recognized, the employers' risk and experience to be charged with such cases. In the event of any such employees, while so engaged, received extra compensation from the employer the same shall be included in the pay roll reports to this department.

The conclusion of the Industrial Commission was that decedent's death was not the result of an injury received in the course of and arising out of his employment.

The question then presented, said the court of appeals, is: Was the death of decedent due to an injury received in the course of his employment with the Crosley Corporation and did such injury arise out of such employment? In view of the facts previously recited, said the court of appeals, and the weight of authority involving similar situations, it seems that there is sufficient relationship in the activity of the deceased at the time of his death to his employment to justify the conclusion that the claimant is entitled to compensation under the constitution and statutes as well as the rule of the Industrial

Commission. It seems also apparent, the court concluded, that both employee and employer received considerations from this activity which was the direct outgrowth of a recreational program which was not only authorized by the corporation, but definitely sponsored by it and the means of its accomplishment furnished at the expense of the corporation. Accordingly, the judgment of the trial court granting an award to the plaintiff was affirmed.—*Ott v. Industrial Commission, 82 N. E. (2d) 137 (Ohio, 1948).*

**Extravagant Claims and Promotional Literature as Misbranding.**—The defendant was charged with introducing, or delivering for introduction, into interstate commerce misbranded drugs. He was tried without a jury and found guilty, and this judgment was affirmed on appeal (*United States v. Kordel*, 164 F. [2d] 913; J.A.M.A. **137**:408 [May 22] 1948). Accordingly the defendant appealed to the Supreme Court of the United States.

The defendant writes and lectures on health foods from information derived from studies in public and private libraries. Since 1941 he has been marketing his own health food products, which appear to be compounds of various vitamins, minerals and herbs. The alleged misbranding consisted of statements in circulars or pamphlets, distributed by the vendors of the products, relating to their efficacy. The defendant supplied these pamphlets as well as the products to the vendors. Some of the pamphlets were displayed in stores in which the defendant's products were on sale. Some of them were given away with the sale of the products; some were sold independently of the drugs, and some were mailed to customers by the vendors. The circulars or pamphlets involved were shipped separately from the drugs and at different times, both before and after the shipments of the drugs with which they were associated. The question whether the separate shipment of the literature saved the drugs from being misbranded within the meaning of the act, said the Supreme Court, presents the main issue in this case.

The federal food and drug act prohibits the introduction into interstate commerce of any drug that is adulterated or misbranded. It is misbranded, according to the Act, if its labeling is false or misleading in any particular, and the term "labeling" is defined to mean "all labels and other written, printed or graphic matter (1) upon any article or any of its containers or wrappers, or (2) accompanying such article."

In this case, said the Supreme Court, the drugs and the literature had a common origin and a common destination. The literature was used in the sale of the drugs. It explained their uses. Nowhere else was the purchaser advised how to use them. It constituted an essential supplement to the label attached to the package. Thus the products and the literature were interdependent, as the court of appeals observed. It would take an extremely narrow reading of the act, continued the Supreme Court, to hold that these drugs were not misbranded. A criminal law is not to be read expansively to include what is not plainly embraced within the language of the statute, but there is no canon against using common sense in reading a criminal law, so that strained and technical constructions do not defeat its purpose by creating exceptions from or loopholes in it. It would, indeed, create an obviously wide loophole to hold that these drugs would be misbranded if the literature had been shipped in the same container but not misbranded if the literature left in the next or in the preceding mail. One article or thing is accompanied with another when it supplements or explains it, in the manner that a committee report of the Congress accompanies a bill. No physical attachment one to the other is necessary.

The false and misleading literature in the present case was designed for use in the distribution and sale of the drug, continued the Supreme Court, and it was so used. The fact that it went in a different mail was wholly irrelevant, whether we judge the transaction by purpose or result. And to say that the prior or subsequent shipment of the literature disproves that it "is" misbranded when introduced into commerce within the meaning of the statute is to overlook the integrated nature of the transactions established in this case. Moreover, the fact that some of the booklets carried a selling price is immaterial on the facts shown here. As stated by the court of appeals, the booklets and drugs were nonetheless interdependent; they were parts of an integrated distribution program. The act cannot be circumvented by the easy device of a "sale" of the advertising matter where the advertising performs the function of labeling. Accordingly the judgment of the trial court and of the court of appeals was affirmed and the defendant was held guilty of a breach of the provisions of the federal food, drug and cosmetic act.—*Kordel v. United States, 69 S. Ct. 106 (1948).*

**Food and Drug Acts: Evidence of Misbranding of Device.**—This was a libel filed under the federal food, drug and cosmetic act seeking seizure of sixteen machines labeled "Sinuothermic." The libel alleged that the device was misbranded within the meaning of the act in that representations in a leaflet, entitled "The Road to Health," relative to the curative and therapeutic powers of the device in the diagnosis, cure, mitigation, treatment and prevention of disease were false and misleading. It charged that the leaflet had accompanied the device in interstate commerce. The respondent appeared as claimant of several of the devices. Judgment of the trial court in favor of the plaintiff was reversed by the court of appeals (*U. S. v. Urbuteit*, 164 F. [2] 245; J.A.M.A. **136**:947 [April 3] 1948) so the government appealed to the Supreme Court of the United States.

The respondent terms himself a naturopathic physician and conducts the Sinuothermic Institute in Tampa, Fla. The machines against which the libel was filed are electrical devices allegedly aiding in the diagnosis and cure of various diseases and physical disorders, such as cancer, diabetes, tuberculosis, arthritis and paralysis. The alleged cures effected through its use are described in the allegedly false and misleading leaflet, "The Road to Health," published by the respondent and distributed for use with the machines. The respondent shipped from Florida a number of these machines to one Kelsch, a former pupil of his who lives in Ohio. Kelsch used these machines in treating his patients, and, though he did not receive them as a merchant, he sold some to patients. As part of this transaction the respondent contracted to furnish Kelsch with a supply of leaflets, which were sent from Florida to Ohio at a different time than when the machines were forwarded. Kelsch used the leaflets to explain the machines to his patients. The leaflets seem to have followed the shipment of the machines. But as *Kordel v. United States* holds, that is immaterial where the advertising matter that was sent was designed to serve, and did in fact serve, the purposes of labeling. This machine bore only the words, U. S. Patent Sinuothermic Trade Mark. It was the leaflets that explained the usefulness of the device in the diagnosis, treatment and cure of various diseases.

The power to condemn, said the Supreme Court, is contained in section 304 (a) of the food and drug act and is confined to articles "adulterated or misbranded when introduced into or while in interstate commerce." We do not, however, read that provision as requiring the advertising matter to travel with the machine. The reasons of policy which argue against that in the case of criminal prosecutions are equally forcible when we come to libels. Moreover, the common sense of the matter is to view the interstate transaction in its entirety—the purpose of the advertising and its actual use. In this case it is plain to us, the court continued, that the movements of the machines and leaflets in interstate commerce were a single interrelated activity, not separate or isolated ones. The act is not concerned with the purification of the stream of commerce in the abstract. The problem is a practical one of consumer protection, not dialectics. The fact that the false literature leaves in a separate mail does not save the article from being misbranded. Where by functional standards the two transactions are integrated, the requirements are satisfied, though the mailings or shipments are at different times. Accordingly the judgment of the circuit court of appeals which was in favor of the respondent was reversed and the libel was granted.—*United States v. Urbuteit, 69 S. Ct. 112 (1948).*

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Ocular Changes Associated with Pheochromocytomas. R. W. Hollenhorst.—p. 226.

**Examinations of Serous Fluids.**—Phillips and McDonald studied one hundred and three specimens of fluid from 92 consecutive patients with ascites, pleural effusion or pericardial effusion who underwent paracentesis, thoracentesis, pericardial aspiration, peritoneoscopy or laparotomy. Specimens were centrifuged at 1,800 to 2,000 revolutions per minute for fifteen minutes, and the sediments obtained were smeared on slides and dried in the air at room temperature. Some of each set of slides were then fixed in 10 per cent solution of formaldehyde for twelve to twenty-four hours, stained with hematoxylin and eosin, and mounted with cover slips in Canada balsam. Other smears were stained with Wright and Giemsa stains in the usual manner for preparing blood smears. Fifty-three specimens of fluid were obtained in 46 cases in which a diagnosis of malignant disease had been made clinically on roentgenologic examination, biopsy or necropsy, but in only 34 cases, in which forty specimens were obtained, was there evidence that the tumor might have involved the serous surfaces. In 19 of the 34 cases a positive diagnosis of malignant disease could be made on the basis of the finding of malignant cells in the fluids. Absence of the characteristic cell did not rule out the diagnosis. The use of Wright and Giemsa stains in addition to hematoxylin and eosin was found to be of assistance in some cases because they revealed the intranuclear detail more clearly. A large cell pack suggested the presence of malignant disease with involvement of the serous surface, but a small cell pack was of no significance in diagnosis. Malignant disease can cause the formation of serous effusions without involvement of the serous surface by tumor cells.

**Antigen Tracer Studies in Anaphylactic Shock.**—Warren and Dixon point out that the location of the antigen-antibody reaction is one of the most disputed aspects of anaphylactic shock. By using an antigen labeled with radioactive iodine and employing tracer technics they have been able to locate significant antigen concentrations during anaphylactic shock. The finding of antigen localized in edematous bronchial fibrous tissue suggested their subsequent study to determine the relation of this localization to bronchial obstruction, which is such a striking feature in death of guinea pigs from anaphylactic shock. They studied the stages in the development as well as the final picture of bronchial obstruction during shock and also the bronchial obstruction produced by various pharmacologic agents acting on smooth muscle. They found that significant amounts of labeled antigen were picked up only by liver and lung during anaphylactic shock. The amount of antigen taken up and its histologic distribution in the liver were the same in sensitized and nonsensitized animals and therefore presumably not related to sensitivity. The affinity for antigen on the part of sensitized lungs in fatal shock was about twice that seen in controls and therefore presumably a function of the sensitivity. The increased amount of antigen taken up by the sensitized lungs was found in the edematous bronchial fibrous tissue. They were unable to confirm the generally accepted assumption that bronchial obstruction of anaphylactic shock results solely from contraction of bronchial smooth muscle. Only in the early stages of shock (within two minutes after the onset of respiratory distress) was there convincing morphologic evidence of smooth muscle contraction; and even in these early stages there was already some edema formation. In the terminal stages of shock, the smooth muscle did not appear contracted or otherwise abnormal. The bronchial edema which began to form during the early stages of shock became massive in the terminal stages and at that time appeared to be the most important factor in the production of bronchial obstruction. Since this edematous zone was the site of antigen localization, it seemed possible that the antigen-antibody reaction was related to the edema formation.

**Immediate Sequelae of Myocardial Infarction.**—According to Selzer, myocardial infarction remains one of the most unpredictable entities in clinical medicine. The reason for this is the multiplicity of factors influencing its course and immediate prognosis, for, in addition to the actual derangement of the circulation caused by myocardial infarction, the course of the disease is often altered by secondary complications. The immediate prognosis of acute myocardial infarction depends largely on the myocardial necrosis and its sequelae. Coronary artery disease is the usual initiating factor in obstructing the blood flow to a portion of the myocardium, but once heart muscle necrosis has developed the damage to the myocardium affects the course of the disease, regardless of whether or not there is progression of coronary arteriosclerosis. A series of 130 unselected cases of recent myocardial infarction found at necropsy was examined. In 35 patients myocardial infarction was a terminal event in otherwise seriously ill patients. The remaining 95 patients were apparently well prior to the onset of the myocardial infarction and were subjected to detailed analysis. The immediate cause of death in this group of 95 cases was: progressive circulatory failure, with or without shock, in 28 cases; sudden death due to arrhythmia in 24 cases; embolic phenomena in 15; cardiac rupture in 8 cases, and secondary coronary thrombosis in 5 cases. In the remaining 15 cases death was due to incidental complications not related to myocardial infarction. No significant correlation was found between the age of the patients, the degree of the coronary arteriosclerosis, the size of the infarction and the presence of myocardial scars and of cardiac hypertrophy on one hand, and the course, the duration of illness and the frequency of complications on the other hand. This is interpreted as indicating the adequacy of circulatory adjustment even in cases with extensive damage to the heart. The prognosis of acute myocardial infarction is unpredictable because the importance of cardiac insufficiency—the direct consequence of the damage to the myocardium—is outweighed by secondary complications. The important sequelae of myocardial infarction, which can be considered potentially preventable causes of death, are serious arrhythmia, thromboembolic phenomena and shock.

Observations in Guinea Pigs Following Injection of Specific Hematopoietic Substances Derived from Urines of Human Leukemic Subjects. A. Sawitsky and L. M. Meyer.—p. 1117.

**Five Year Survival After Gastrectomy for Cancer.**—Steiner and his associates report on 30 cases in which the patients lived five years or longer after resection of a gastric cancer. All these conformed to the standard criteria for malignant tumors. A control group was used for comparison. It was composed of 30 cases of carcinoma of the stomach in which the patients had undergone resections similar to those of the five-year survivors, had survived operation, but had died of local recurrence or metastases within one year after operation. For a few comparisons with the five-year survivors, the entire clinical group of 576 cases of gastric cancer was used. Factors associated with five-year survival were sharp circumscription of the tumor, two special histologic types of cancer and a characteristic degeneration of tumor cells. Twenty-five of the five-year survivors would have been given a bad prognosis because they were in microscopic grades 3 and 4. Only 4 of the 30 five-year survivors would have been given a good prognosis by a combination of microscopic grades 1 and 2 and macroscopic types I and II. The error obviously would have been large by these methods. Five-year survival after gastrectomy for cancer may be due to cure by complete extirpation or to slow rate of recurrence. The relative importance of these two factors cannot be determined until the outcome is known. The chief defect in macroscopic typing as a method for estimating prognosis lies in its inability to detect the finer degrees of circumscription of the tumor. The chief defects in histologic grading are the failure to recognize the favorable course of a few special types of undifferentiated cancer and the importance of circumscription and retrogressive changes in the tumor.

**Basic Patterns in Teratoid Tumors of Testis.**—Moon and Hullinghorst report 125 tumors of the testis, of which 121 were of the teratoid type. Only three fundamentally distinct patterns, namely, seminoma, teratoma and carcinoma, could be demonstrated consistently in the group of teratoid tumors. These three patterns were encountered with about equal frequency. The seminoma pattern was encountered in 55, the teratoma pattern in 55 and the carcinoma pattern in 61 tumors. In 75 tumors a single pattern was present. There were 44 pure seminomas, 13 pure teratomas and 18 pure carcinomas. In 46 tumors various combinations of the three basic patterns were present. The teratoma-carcinoma combination was the most frequently observed, and this was seen in 35 cases. The seminoma-teratoma combination occurred in 3 cases, the seminoma-carcinoma combination in 4 cases and the seminoma-teratoma-carcinoma combination in 4 cases. The mean age for the entire group of patients with teratoid tumors was 29 years. There were 26 fatalities, and in these the seminoma pattern occurred three times, the teratoma pattern fourteen times and the carcinoma pattern twenty-one times. The definite tendency of the teratoma and carcinoma patterns to occur in the same tumor again was noted, and in 11 of the fatal cases this combination was present. Only 2 deaths occurred in the pure seminoma group and 2 deaths in the pure teratoma group, whereas 10 deaths occurred in the pure carcinoma group.

**Pulmonary Adenomatosis.**—Drymalski and his co-workers say that a multiple, nodular, bilateral tumor of the lungs was first described by Helly in 1907. Because of the preservation of the alveolar septums which were lined with cylindric cells and the absence of metastases, he termed the growth an adenoma, as distinguished from an alveolar cell carcinoma. Since Helly's report, 12 cases have been described in the literature, and to this number the authors add 3 more cases. Among the total of the 15 cases there were 9 women and 6 men. Their average age was 54 years. The duration of the disease has varied from several weeks to over two years. The 3 cases of pulmonary adenomatosis presented in this paper were detected among 57 cases of carcinoma of the lung. Case 1 of the 3 cases is the second recorded surgical specimen of this condition and indicates a possible bronchogenic origin for the disease. Case 2 illustrates malignant proliferation of the cells of the adenomatous process. The cuboidal epithelium lining the air sacs and the loss of normal pulmonary architecture in case 3 represent an unusual variety of adenomatosis of the lung. Representing about 5 per cent of all pulmonary tumors, adenomatosis of the lungs resembles the so-called alveolar cell carcinoma in all respects. Probably the result of nonspecific irritation, the hyperplastic reaction of pulmonary adenomatosis is aggressive and may develop all the characteristics of malignancy. There are no distinguishing clinical features of pulmonary adenomatosis.

**Activity of Minimal Pulmonary Tuberculosis.**—According to Birkelo and Rague the photofluorogram is valuable in the solution of the twofold problem of tuberculosis control: finding the infective source for the purpose of isolating it and finding the early case at a stage amenable to therapeutic measures. Its introduction has raised new questions. Growing numbers of "positives" are being discovered with the result that sanatorium and hospital facilities threaten to be swamped unless criteria which are reliable, yet simple in application, are established as guide in the disposition of the newly discovered case. A negative reaction to a skin test is strong evidence that the lesion is not tuberculous. Those who feel that reactors with positive roentgenograms can then be divided into active and inactive, or even tuberculous and nontuberculous, categories on the basis of sputum examinations or gastric aspirations take too sanguine a view of the problem. Unless the samples are collected under observation there is always the possibility of deliberate substitution of sputum samples. Scheduling patients for a number of gastric aspirations presupposes a degree of enlightened cooperation not always encountered in patients. The authors outline the methods used at the Detroit Department of Public Health. They conclude that activity can be determined accurately by roentgen examination and more rapidly and economically than by bacteriologic methods. In a group of 699 cases of minimal tuberculosis followed for two to five years, activity was correctly determined from the first roentgenogram in 86.43 per cent. Success in such a program depends on the services of an experienced roentgenologist and the use of the large film. The photofluorogram should be used for screening only. Patients with minimal inactive pulmonary tuberculosis should be followed by roentgen examinations at three month intervals for two years from the time of discovery and at longer intervals for an indefinite period thereafter.

**Irradiation of Pituitary Tumors.**—Kerr reports 50 cases, 11 of which were of the acidophilic type, 1 the basophilic, 37 the chromophobic and 1 the mixed acidophilic and chromophobic. Irradiation should be used first in the treatment of pituitary tumors, and only if this fails should the patient be operated on. The method of irradiation used by Kerr differs from other present day technics only in that he does not give repeated courses but tries to deliver in one course the dose necessary to produce regression. Radiation is directed toward the sella turcica through four fields (two temporal, one frontal and one vertical). He uses 200 kilovolts, with a 1.95 mm. copper half-value layer, 50 cm. distance and a 5 cm. cone. One hundred roentgens are given to one field the first day in order to reduce to a minimum the chances of causing swelling with increased intracranial pressure and headache. If no reaction ensues, two fields are given 100 r each the second day and from then on 200 r are given to each of two fields per day. This is carried up to a total of 2,000 r per field (air dose). With the ordinary-sized calvarium, this delivers approximately 2,400 r into the pituitary fossa. Results of irradiation in 24 patients treated six years ago seem permanent. Observations on a total of 50 cases emphasize that irradiation is a satisfactory primary method of treatment. The good results are in the range of 70 per cent. The chromophobic tumors respond as well as the acidophilic. It is important to follow the results of treatment carefully for at least two months, particularly regarding the visual fields. If there is diminution of the fields at that time, the neurosurgeon should be called in consultation because the tumor is either cystic or otherwise radioresistant. Psychotic patients or patients with previous cerebral symptoms will probably not do well and may have their symptoms exaggerated. It is questionable whether they should be irradiated. There may possibly be occasional cerebral damage from irradiation, although this has not been definitely proved.

Diagnosis in Primary Cancer of Bronchus. J. A. Crellin and T. F. Pugh.—p. 109.

**Treatment of Angina Pectoris.**—Thompson ligated the descending branch of the left coronary artery of dogs just below the circumflex branch, and death resulted in about 50 per cent of the animals. In a second group of dogs the same ligations were done, but these animals also had U.S.P. talc powder (hydrous magnesium silicate) instilled inside the pericardial sac to produce pericardial adhesions. In this group the mortality was 25 per cent. In a third group of dogs adhesive pericarditis was produced by the use of talc powder inside the pericardial sac, and two to three weeks later the same ligations were performed. In this group the mortality was zero. The talc powder inside the pericardial sac produces a decided foreign body reaction with resulting hyperemia of myocardium, epicardium and pericardium. It also produces adhesive pericarditis. This leads to the establishment of an extracardiac collateral circulation from the adherent pericardium and to the development of a collateral circulation in the heart muscle. The production of adhesive pericarditis by this method is in no way constrictive and does not add any extra burden to the work of the heart. Approximately 2 drachms by volume of dry sterile U.S.P. talc powder were distributed widely over the visceral pericardial surface inside the pericardial sac of 36 patients under general anesthesia, who were completely incapacitated preoperatively because of anginal pain. In determining the final results of the operation the relief of pain was considered of prime importance. Six patients died in the hospital after operation, 5 from coronary occlusion and 1 from a rupture through an unhealed infarct. Twenty-one patients showed definite improvement, and 8 of these patients consider themselves to be normal. Five patients were moderately improved and 4 patients still have the anginal pain but show some slight improvement in the exercise tolerance. The operation is simple and requires a short time for completion. Two principal contraindications are congestive failure and an active myocardial infarct. The selections of patients for operation depends on definite criteria. Not all patients with coronary artery disease and angina should be operated on. In view of the extreme degree of incapacity and the amount of myocardial pathologic change, the results of this form of treatment are very satisfactory.

**Bronchiectasis.**—According to Barach, the presence of bilateral, extensive bronchiectasis in a large number of patients prevents the use of surgical procedures. In the majority of these cases inhalation of 400,000 to 500,000 units of penicillin aerosol daily in successive four to six week courses has resulted in decided improvement in the patient's condition, with decrease in cough and expectoration and a striking diminution of the purulent quality of the sputum. Topical application with an aerosol of penicillin not only achieves a therapeutic blood level but also exercises a bacteriostatic influence on organisms developing on the bronchial mucous membrane. Favorable results have been observed in cases that have shown little or no benefit from systemic administration of the drug. Of fifty-nine courses of therapy in 35 patients with bronchiectasis there was marked improvement in 15, moderate in 22, slight in 14 and none in 8. Of seven courses of therapy in 5 patients with acute lung abscess, marked improvement occurred in 4, slight in 2 and no improvement in 1. Of four courses of therapy in 3 patients with chronic lung abscess, two resulted in marked improvement, one in slight improvement and one in no change. Of twenty-four courses of therapy in 16 patients with chronic bronchitis, improvement was pronounced in 12, moderate in 8, slight in 1 and absent in 3. Penicillin aerosol therapy constitutes an effective and practical technic which may be added to other forms of treatment in the management of patients with bronchopulmonary suppuration.

Balanced Anesthesia for Thoracoplasty. C. L. Hebert.—p. 537.

**Controlled Hypotension by Arterial Bleeding.**—According to Hale, a fall in blood pressure and an increase in vasoconstriction account for the diminished bleeding following withdrawal of blood from the radial artery. This device for withdrawing blood before operations lessens surgical hemorrhage and expedites surgical intervention, at the end of which the blood is returned through the artery. The blood may be returned earlier in the event of severe decrease in blood pressure. This procedure of controlled induced hypotension was used in 50 patients, 25 women and 25 men between the ages of 14 and 60, on 24 of whom craniotomy and on 26 of whom the fenestration operation was performed. Preanesthetic medication consisted of pentobarbital, morphine sulfate and atropine sulfate, administered by mouth or rectum and by hypodermic injection within several hours before operation. Anesthesia was induced by intravenous injection of thiopental sodium supplemented by nitrous oxide and oxygen or by oxygen alone. The average patient weighed 156 pounds (70.8 Kg.); 1742.6 cc. (2.4 per cent of body weight) of blood was collected. The blood was withdrawn over a period of 29.4 minutes and remained outside the body for 25.7 minutes. The systolic blood pressure fell from a prebleeding level of 118.2 to a low of 75.9 mm. of mercury, this fall occurring within 13.3 minutes of the maximum bleeding. Of the blood withdrawn 500 cc. is permanently withheld from patients on whom the fenestration operation is performed. It was noted that these patients complained less of nausea, vertigo and headache, probably owing to the diminished postoperative edema incident to the mild dehydrating effect of the blood loss. The amount of heparin used as coagulant in the average case does not exceed 100 cc. of 0.01 per cent solution. This has been of no practical consequence in causing an increase in bleeding at the operative side. Electrocardiographic tracings were made on 3 patients before bloodletting, after the maximum amount of blood had been withdrawn and after infusion. Significant changes were not observed. Controlled induced hypotension is a valuable procedure for controlling hemorrhage in craniotomy and the fenestration operation.

**Spot Test for Syphilis.**—Lane says that for some time after its inception the Meinicke clarification test for syphilis was treated with suspicion on the grounds of nonspecificity, reactions supposedly taking place in malaria and tuberculosis. The Wassermann test likewise is not entirely specific, in that it sometimes produces positive results in the absence of syphilis in such conditions as pregnancy, malaria and infectious mononucleosis. The Meinicke is a colloidal test which employs a cardiac extract plus tolu balsam as the antigen. Solutions of sodium chloride constitute the electrolyte. The prepared antigen has a milky opaque appearance. Precipitation of the colloids takes place when the antigen is brought into contact with a syphilitic serum or cerebrospinal fluid, and clarification takes place because of sedimentation of the precipitated colloids. A normal serum or cerebrospinal fluid has no effect on the colloidal state; the mixture remains milky and opaque. The author's laboratory formerly used Meinicke's original antigen, but for some years he and his co-workers have been using the modified antigen of Ford Robertson and Colquhoun. The Meinicke test has the disadvantage that about eighteen hours of wait is involved. The modification employed by the author, which is a spot test, is free from this disadvantage. The reaction time is reduced to ten minutes. It has been used in parallel with the standard Meinicke technic and the Wassermann test in 858 specimens of serum and 142 of cerebrospinal fluid. The results with the rapid method (spot test) were in agreement with the Wassermann reaction in 97.5 per cent of the tests, while the results with the standard Meinicke test were in agreement with the Wassermann reactions in 98 per cent of cases. The results obtained from tests of cerebrospinal fluid are comparable with those for blood.

**Granuloma Inguinale.**—The shifts of population which accompanied the recent war resulted in a hitherto unprecedented number of cases of granuloma inguinale in the North. Thus, in three years, in the city of Chicago, where the disease was rare, 97 patients were treated at the Intensive Treatment Center. Marshak and her associates say that patients seen early in this study were treated on an outpatient schedule. Many of these discontinued their visits. All patients seen from March 1946 to November 1946 were hospitalized. There was a gratifying response to a 1 per cent solution of antimony potassium tartrate given intravenously in even the old neglected cases. The dose of the drug ranged from 1 to 10 cc., in ascending doses of 1 cc. per day gradually, and after the maximal dose was reached a decreasing dose, by 1 cc. per day, was administered for the next ten days. A total of 100 cc. of antimony potassium tartrate was given. Twenty-one of the 25 patients thus treated exhibited complete healing. In 1 of the patients in whom antimony drugs had been ineffective, streptomycin was employed with brilliant results. Results obtained in this patient and in 3 others demonstrate the efficacy of this drug in this disease. A small dosage of streptomycin was effective in healing the lesions.

**Systemic Reticuloendothelial Granuloma.**—Laymon and Sevenants show that there is considerable evidence that Letterer-Siwe disease, Schüller-Christian disease and eosinophilic granuloma represent variations of a basic disorder of the reticuloendothelial system. Letterer-Siwe disease, since it is rapidly fatal, usually does not show the lipidization of the lesions seen in the more protracted Schüller-Christian disease. Eosinophilic granuloma of bone shows lesions which clinically, roentgenologically and histologically cannot be distinguished from comparable lesions in Letterer-Siwe or Schüller-Christian disease. The absence of lipophagic foam cells in many of the lesions of Schüller-Christian disease and the fact that lipemia is hardly more constant in Schüller-Christian disease than in other types of reticuloendotheliosis cause doubt that Schüller-Christian disease is a primary disturbance of the lipid metabolism. Although at present it is impossible to draw conclusions concerning cutaneous eosinophilic granuloma, it would seem logical, because of the histologic similarity, tentatively to group this condition with the others under discussion. The cutaneous manifestations of the systemic reticuloendothelial granulomas are subject to considerable variation. In the Letterer-Siwe type there is a noteworthy tendency to cutaneous hemorrhage. Necrotic oral lesions have also been reported. In the Schüller-Christian type the commonest eruptions are the diffuse papular or seborrhea-like types. In 2 cases reported by the authors the eruptions simulated keratosis follicularis. Eosinophilic granuloma of the skin is characterized by nodules, plaques or tumefactions, which may be smooth, ulcerated or verrucous and may be located on various parts of the body.

**Bone Marrow in Multiple Myeloma.**—Bayrd reports 71 cases of multiple myeloma treated at the Mayo Clinic. In 51 of these bone marrow studies were made by sternal aspiration. Pathologic cells in bone marrow smears in multiple myeloma resemble the plasma cell and vary from the very anaplastic and immature cell to the well differentiated and almost characteristic plasma cell. The feature which the "myeloma" cell shares with the plasma cell is the abundant, granular, basophilic cytoplasm which tends to be fragile and undergo the same degenerative changes in each, namely the formation of Russell bodies and vacuolization. Fairly frequently a perinuclear clear area or Hof is present and the nucleus tends to be eccentrically placed. Cytoplasmic extensions or pseudopodia may also be seen in either case, but they occur more often and more dramatically in instances of multiple myeloma. Multinucleated cells are commonly seen. Myeloma plasma cells often have a large clear nucleolus and a leptochromatic nucleus and exhibit a tendency to formation of isolated areas of condensed chromatin. Cytoplasmic extrusions, free cytoplasmic bodies, occasionally complete with Russell bodies and vacuoles, are almost universally present. All cases were of the plasma cell type; there was no exception. In these cases the myeloma plasma cell constituted from 2.5 to 96 per cent of the leukocytic elements present. It is suggested that all so-called types of multiple myeloma are merely variations in differentiation of this same cell. Anaplasia, hypernucleation and lack of plasma cell predominance in certain cases were diagnostic pitfalls. Additional evidence was adduced to confirm the reticuloendothelial origin of the myeloma plasma cell. Ten cases in which there was decided pleomorphism, often associated with frequent mitoses and immaturity, bore the poorest prognosis, and none of the patients in this group survived longer than twelve months after the onset of symptoms. Patients in whom uniform, mature-appearing plasma cells comprised almost the entire number of myeloma cells present survived forty-two to eighty-eight months after the onset of symptoms.

**Chronic Brucellosis.**—Griggs reports a follow-up questionnaire returned by 133 of 222 patients who had begun treatment with oxidized Brucella abortus or suis vaccine one to six years previously. Of the 133 a total of 112 patients were improved, 18 were not improved and 3 were worse. Success in treatment appears to be correlated with certainty of diagnosis. Therapeutic factors other than vaccine did not appear to be of much importance in this series of patients. A study of the degree of improvement achieved showed that only about 14 per cent recovered completely, 28 per cent reported a "very good result," another 28 per cent a "good result" and 13 per cent only a fair improvement. Unfavorable prognostic factors in chronic brucellosis are extreme hypersensitivity to brucella substances, advanced age, long duration of the illness, inaccessible brucellar foci and other complications. About half of the patients manifested rather severe hypersensitization to brucella at some stage of their course. Avoidance of this manifestation during diagnosis and treatment is important to success. Self administration of the vaccine by patients is feasible after the first few weeks or months of the physician's instruction and demonstration. The rate of relapse varied between 22 and 49 per cent. This study supports the view that chronic brucellosis is a complicated disease entity which is difficult to prove and which is worthy of careful treatment with vaccine until a more effective agent is discovered.

**Cytologic Studies in Primary Carcinoma.**—Farber and his co-workers raised the sputum of patients with pathologic conditions of the lung from the bronchial passage by deep coughing. The smears were immersed immediately while still wet in a fixative solution consisting of equal parts of ether and 95 per cent ethyl alcohol. Papanicolaou's trichrome stain was used exclusively because of the transparency of the counterstain obtained by the use of solutions of a high alcohol content. Secretions obtained at bronchoscopy were smeared and fixed in the same manner as sputum. This method was employed for cytologic examination in a series of 1,755 specimens from 500 patients. It proved useful in suggesting, establishing or confirming the diagnosis of carcinoma of the lung. Malignant cells were demonstrated in 82 patients. Of these 82 patients, 57 have been proved to have carcinoma of the lung by tissue section. In the total series of 500 patients, 71 have been proved to have bronchogenic carcinoma, and in 57 (80 per cent) of these cases malignant cells were demonstrated. There is a close correlation of the results obtained by using either sputum or bronchial secretions. The use of sputum is more practical. Criteria for the cytologic diagnosis of cancer are discussed. The cytologic examination of the sputum is a valuable addition to the procedures for the diagnosis of carcinoma of the lung.

**Streptomycin and Tuberculosis.** — In Buenos Aires, Albertal and his co-workers treated 50 patients with pulmonary tuberculosis with 1 Gm. of streptomycin daily in five divided doses. The selection of the patients was not based entirely on the indications accepted for the use of streptomycin in the United States and England, but was partially governed by the ability of the patient to obtain this drug and by the demands of the patient's relatives for its use. Results showed that streptomycin treatment is indicated (1) for general therapeutic purposes in cases of acute, subacute or chronic hematogenous tuberculosis and for hematogenous lesions of the early exudative type; (2) for treatment of laryngeal and intestinal lesions regardless of the form or course of the associated pulmonary tuberculosis; (3) for restricted therapeutic purposes in any clinical form of pulmonary tuberculosis, for extrapulmonary lesions, for pulmonary tuberculosis complicated by diabetes mellitus or for cases of pulmonary tuberculosis and pregnancy. Because of the satisfactory results of preparatory treatment with streptomycin, collapse therapy may be feasible in cases in which it could not be considered previously because of the type of the lesion, the advanced stage of the disease and the precarious general condition of the patient.

Community Organization for Older Persons. E. H. Moore.—p. 306.

**Diet in the Aged.**—Rafsky and Newman reported in previous articles the tendency in aged persons to what may be termed "biochemical avitaminosis." By the term "biochemical avitaminosis" is meant laboratory findings of avitaminosis without clinical evidence of deficiency disease. This phenomenon was reported in studies on ascorbic acid, nicotinic acid and its relationship to porphyrinuria and thiamine and its relationship to gastric acidity, and in studies on several phases of carotene and vitamin A metabolism. The authors studied the dietary habits of apparently normal persons past the age of 65 years. The 65 subjects were divided into four groups and were observed for seven consecutive days each. A total of twenty-eight days was required for the entire experiment. The persons were given the usual diet served in the institution. They were permitted to eat as much as they desired. The authors conclude that the fact that laboratory evidence of nutritional deficiency exists in apparently normal aged persons cannot, on the basis of this study, be attributed to faulty dietetic intake or to a diet which is lacking in fat, carbyhydrate or proteins, or to a diet which produces insufficient caloric energy. Previous studies likewise stressed this fact. Since the state of "biochemical avitaminosis" which exists in aged persons cannot be explained by an inadequate diet, it is necessary to look elsewhere for the cause.

**Peripheral Arterial Disease in the Aged.**—Samuels feels that arterial insufficiency of the legs in aging and aged persons is an important factor in their lives, but that in many cases the family doctor attaches too little significance to this condition, which, in some instances, may be more damaging than similar disease of the coronary arteries. Frequently the onset of gangrene in elderly persons is the first intimation that they may have trouble with the circulation in the lower extremities. The most frequent method of onset of gangrene is mycotic infection of various parts of the feet. The usual foci of fungous infections in the feet are the interdigital spaces and any area of the foot where there is an accumulation of dead epithelium. These are usually found in corns, calluses and the eponychia around the toe nails. Careful investigation of the onset of gangrene in elderly persons will usually elicit a history of trauma induced by the patient rather than "spontaneous" occurrences, which is the usual idea. The author makes numerous therapeutic suggestions. Peripheral arterial disease in the aged is not a hopeless and helpless condition as previously thought. Fungicidal measures are an extremely important part of the prophylactic care. Intelligent management, rather than vasodilating procedures, is of paramount importance. Gangrene in the aged may be successfully treated by conservative methods. When amputation is indicated the operation should be above the knee by the simplest method. Elderly patients should be out of bed the day after operation.

**Biologic Effect of Irradiation by Radioactive Iodine.**—Skanse points out that tracer doses of radioactive isotopes have been used in biology and medicine with the assumption that their radiation does not change the physiology under investigation. The author has undertaken studies with radioactive iodine ($I^{131}$) in doses which have been used as "tracers" with two main objectives: (1) to determine the minimal amount of radioactive iodine which may interfere with the normal function of the thyroid and (2) to study the effects of irradiation by radioactive iodine on various known functions of the thyroid. Five day old cockerels were given injections of 0.5 unit of thyrotropic hormone for three consecutive days. Twenty-four hours after the last injection three groups were given subcutaneous injections of $I^{131}$ (containing 0.1 microgram sodium iodide as a carrier) in doses of 1, 10 and 50 microcuries, respectively. A fourth group received no radioactive iodine and was used as a control. It was found that during the first 96 hours no physiologic change took place in the thyroid at any dose level. The earliest radiation effect was observed in the 50 microcurie group 144 hours after administration of the isotope. This indicated that the thyroid does not retain a large dose of $I^{131}$ as well as it does a smaller one for any extended period. Thyroids of chicks which had received 1 millicurie of $I^{131}$ did not change in growth or iodine concentration. In animals which received 10 millicuries and 50 millicuries the normal growth of the thyroid was significantly inhibited. Iodine concentration was not altered in the animals which received 10 millicuries, but there was a significant decrease in concentration of thyroid iodine in the 50 millicurie group. All irradiated animals responded to thiouracil as measured by increase in thyroid weight twenty-six days after administration of $I^{131}$. However, thirty-eight days after they received $I^{131}$ there was no longer any response to thiouracil in the 50 millicurie group and in the 10 millicurie groups the response was not as great as in the nonirradiated controls. An investigation of the effect of $I^{131}$ on the thyroid's response to thyrotropic hormone showed that all irradiated animals responded to thyrotropic hormone as measured by increase in thyroid weight and loss of iodine sixteen days after administration of $I^{131}$. At the twenty-four day interval there was demonstrated a dissociation in response to thyrotropic hormone between the 10 millicurie and the 50 millicurie group. In the 10 millicurie group a loss of iodine was observed but no increase in thyroid weight. In the 50 millicurie group there was no effect on thyroid weight and the loss of iodine was minimal.

**Appraisal of Goitrogens.**—According to Bartels five years have now elapsed since Astwood's first report on the use of thiouracil in clinical hyperthyroidism. Since then reports are available on experiences with propylthiouracil and more recently with methylthiouracil. All observers agree that these agents alleviate the symptoms of hyperthyroidism when given in sufficient dose. That their action is specific in preventing the formation of organic iodine or thyroxin from inorganic iodine has been firmly established. The effective dose of thiouracil, propylthiouracil and methylthiouracil is 600 mg., 200 to 300 mg. and 200 to 300 mg., respectively. The incidence of toxic reactions is 9 per cent for thiouracil, 2 per cent for propylthiouracil and approximately 10 per cent for methylthiouracil. Investigators are in agreement as to the great benefit of these drugs as preoperative adjuvants. Difference of opinion existed regarding their value as substitutes for surgical treatment. The reported incidence of remissions after drug treatment shows wide variations. Some observers report remission in as high as 80 per cent of cases and others in as low as 20 per cent, with the remissions varying from a few months to two years. No satisfactory criteria exist to judge the duration of treatment required to produce a prolonged remission. When prolonged or maintenance treatment becomes necessary, then opinion differs as to the advantages of maintenance antithyroid over surgical treatment of hyperthyroidism. The disadvantages or objections to prolonged medical treatment are many. Most experienced clinicians are in accord that all adenomatous goiters should be removed, because of the risk of malignant disease and of pressure on other structures in the neck.

*Production of Atheromatosis in Aorta of Bird by Administration of Diethyl-Stilbestrol. I. L. Chaikoff, S. Lindsay, F. W. Lorenz and C. Entenman.—p. 373.

**Influence of Humidity on Infectivity of Influenza Virus.**—Lester presents a study on the effect of varying relative humidities on the infectivity of air-borne influenza A virus, as shown by the ability of this virus to produce death or lesions in white mice under conditions in which the potency of the virus suspension, the dose of the virus and the physical environment could be carefully controlled. An amount of atomized virus suspension which produced a 100 per cent mortality rate in animals exposed at 30 and 80 per cent relative humidity, respectively, resulted in the death of only 22.5 per cent of mice at a humidity of 50 per cent. The humidities between these values gave intermediate results. The infectivity of the air-borne virus decreased so rapidly at a humidity of 50 per cent that it was impossible to secure a 100 per cent mortality rate in the exposed mice even by greatly increasing the dose of virus atomized. The use of a dialyzed virus suspension at a humidity of 50 per cent resulted in the death of all exposed mice. This suggested that the deleterious influence of humidity was related to the presence of sodium chloride in the atomized suspension. These findings closely resembled those obtained by Dunklin and Puck with pneumococci, streptococci and staphylococci, which would suggest that the factor responsible for the lethal effect of humidity is common to moist particles containing either the aforementioned bacteria or influenza A virus.

**Production of Atheromatosis with Diethylstilbestrol.**—Chaikoff and his co-workers say that avian lipid metabolism differs from mammalian in being under the control of ovarian hormones. In the bird actively engaged in egg laying there occurs a rise in the levels of fat, phospholipid and cholesterol of the blood; in this state total lipids of the blood may rise as high as 4,000 mg. per hundred cubic centimeters, as compared with values of 500 mg. in the nonlaying state. This rise in the various lipid constituents of the blood could be reproduced in the immature female or male bird by the injection of estrogenic compounds. In birds treated with diethylstilbestrol, values for plasma lipids as high as 10,000 mg. per hundred cubic centimeters have been observed. This distinctive feature of the lipid metabolism of the bird made possible the development of a new method for the study of experimental atherosclerosis. Atheromatosis could be induced in a bird by the administration of diethylstilbestrol. The diethylstilbestrol-induced lesion more closely resembled the spontaneously occurring one in the bird than did that produced by cholesterol feeding. But all three lesions were fundamentally similar, differing only in the amounts and proportions of the various lipid constituents present. The concentrations of cholesterol in plasma of the diethylstilbestrol-treated and cholesterol-fed birds were of the same order. Yet cholesterol constituted a greater proportion of the lipids deposited in the arterial wall of the cholesterol-fed than in that of the diethylstilbestrol-treated birds. This finding suggests that the cholesterol content of the vascular lesion depends not only on the absolute concentration of cholesterol in plasma, but also on the proportion of cholesterol to other lipid constituents in plasma.

**Nonmalignant Achlorhydric Stomach.**—Appleby reports 32 patients, 15 men and 17 women between the ages of 22 and 69, 23 of whom had gastric ulcers and 9 had duodenal peptic ulcers in the presence of achlorhydria. These patients were all treated by acid replacement therapy for some time prior to resection, and with fair success from the standpoint of their anemic and hypoproteinemic standards, but replacement therapy proved ineffective with respect to the persistence of the ulcer and to the persistence of its activity. Peptic ulcer is not caused, nor caused to persist, by acid alone, and yet the presence of acid has much to do with the intensity of pain which is believed to be of muscular origin. The absence of severe pain symptoms incident to the acidity—i.e., the atypical symptom complex—causes many of these cases to go unrecognized. The acceptance of the diagnostic challenge of achlorhydria is strongly urged. Local resection rather than gastric resection is the operation of choice. There has been no operative mortality in these cases. Two additional female patients, aged 50 and 43 respectively, with achlorhydric stomach and resulting surgical complications are reported; intramural gastric abscess containing fish bones projecting into the lesser omental attachment and fish bone perforation of Meckel's diverticulum were demonstrated respectively on surgical intervention. These 2 cases indicate the dangers inherent in simple unrecognized anacid states and suggest the need for more careful dietetic screening of known cases of anacidity.

**Cancer of the Rectum.**—Bacon and Giambalvo report 640 patients, 352 men and 288 women between the ages of 17 and 85, with cancer of the anus, rectum and sigmoid colon. The highest incidence was in the age group between 51 and 60 years. Adenocarcinoma was demonstrated in 618 and epithelioma in 14 patients. The tumor was graded according to Broder's classification in 592 instances, with the largest group of 311 cases in grade II. Nodal metastasis occurred in 4 of 14 cases with involvement of one quarter the circumference, in 11 of 25 cases with involvement of one half the circumference, in 8 of 16 cases with the involvement of three fourths the circumference and in 16 of 25 cases with involvement of the entire circumference. The dictum that the more anaplastic the neoplasm the higher the incidence of lymphatic metastasis has been substantiated. Bleeding is the most constant and one of the first symptoms and was cited in 547 cases (85.6 per cent). Three hundred and forty-three patients (53.7 per cent) complained of constipation and recalled the increasing need of laxatives. A tendency toward diarrhea ensued in 202 patients (31.7 per cent). Sensation of unsatisfactory bowel movement was mentioned by 268 patients (41.9 per cent). Pain is not an early symptom of rectal cancer. Resection was instituted in 514 cases with 27 deaths, a mortality rate of 5.2 per cent. The technic of abdominoperineal proctosigmoidectomy, without colostomy and with preservation of both the external and the internal sphincter muscles, was employed in 344 procedures. In this group there were 17 deaths, a mortality of 4.9 per cent. The survival rate for five years and more was 52.6 per cent; the five year cure rate for grade A tumors, according to mural penetration, was 93.3 per cent. The local recurrence rate based on those patients on whom proctosigmoidectomy was performed five or more years ago was 17.9 per cent.

**Diet and Cirrhosis of Liver.**—In a previous communication Wade and his co-workers described a regimen for the treatment of cirrhosis of the liver which was based on two assumptions: (1) that fatty changes in the liver ordinarily precede the more characteristic anatomic lesions of cirrhosis, and (2) that fatty changes in the liver may be dietary in origin, especially in the alcoholic patient. The results attributed to the therapy were striking. Not all patients responded so dramatically, and spontaneous remissions occurred in the absence of therapy. Interpretation of the efficacy of the therapeutic regimen therefore had to await the study of an increased number of patients over a longer period of time. The present report summarizes the clinical experiences of the past five years, during which time some 224 patients with cirrhosis of the liver were studied. The fate of these patients is compared with that of a similar control group of patients treated in the same hospital under similar circumstances prior to the use of the present therapeutic regimen. The authors arrive at the conclusion that low fat diets supplemented by 1 to 8 Gm. of choline and 1 quart of skimmed milk daily (0.9 Gm. methionine) failed to influence the life span of patients with cirrhosis of the liver, even though these patients were much more closely supervised than the control series.

*Compression of Cervical Spinal Cord by Herniated Intervertebral Disks. P. C. Bucy, R. F. Heimburger and H. R. Oberhill.—p. 471.

**Spinal Nerve Injury in Protrusions of Lumbar Disks.**—Lindblom and Rexed made an anatomic study of the incidence of lumbar disk degenerations on cadavers. The specimens were taken from 160 patients of 14 to 87 years of age, regardless of clinical symptoms and cause of death. Among these, 60 nerve compressions were found, most of them by dorsolateral protrusions against the lateral part of the intervertebral canal, where the nerves with their ganglions cross the corresponding disk. The purpose of the present investigation was to determine the extent of nerve damage in the dorsolateral disk protrusion. In 17 cases of intervertebral disk protrusions where a macroscopic postmortem examination showed the presence of compression of spinal nerves and ganglions, 44 segments were examined histologically by serial sectioning of the damaged nerves and also of corresponding normal nerves. The compression was shown to have caused serious injury to the nervous structures. Diffuse degenerations mixed with regenerative processes of varying intensity were found, especially in the ventral root fibers. The spinal ganglion cells were often definitely deformed and atrophied by the pressure, and the spinal ganglion as a whole showed an increased amount of connective tissue and gross alterations of its internal structure. The severity of the nerve injury was proportional to the degree of macroscopic compression. Occasionally, osteoarthritic enlargement of the intervertebral joints was found to be an accessory factor in causing nerve damage. In 1 case an osteophyte was the only factor responsible for compression of the spinal ganglion. The authors describe the mechanism of compression and the spatial relationship between nerves and surrounding structures in the intervertebral canal. They also mention the relationship between the nerve injury by disk protrusions and certain arachnoidal proliferations around the spinal roots.

**Compression of Cervical Cord by Herniated Disk.**—Bucy and his associates present 4 cases of median herniations of the cervical intervertebral disks with compression of the spinal cord and stress that a herniated cervical intervertebral disk should be suspected whenever in a young or middle-aged man, who is otherwise healthy, either a Brown-Sequard syndrome develops or a spasticity of both legs with considerable difficulty in walking and in maintaining his balance. The absence of symptoms referable to the neck and upper extremities is of little importance. It may be difficult or impossible to differentiate a herniated disk from a tumor in the cervical part of the spinal cord. That is of little importance, as both would be treated surgically. The possibility of confusing a herniated cervical intervertebral disk with multiple sclerosis, primary lateral sclerosis or amyotrophic lateral sclerosis is a serious matter, as the herniated intervertebral disk can be removed and the neurologic symptoms relieved if the operation is performed promptly enough, whereas as yet there is no effective treatment for the degenerative diseases. Every patient suspected of suffering from a degenerative disease of the spinal cord should have a lumbar spinal puncture, and if there is any suspicion that there might be a herniated cervical intervertebral disk a myelogram with "pantopaque" (ethyl iodophenylundecylate) or iodized oil U.S.P. should be made. This rule should be followed even though there is no evidence of block on Queckenstedt's test and the spinal fluid is normal. Myelography carries with it little or no risk and, if the contrast medium is removed at the conclusion of the examination, as it can and should be, there should be no sequelae. These herniations are best removed transdurally through a bilateral laminectomy of at least two vertebrae. The results of such operations in early cases should be excellent, but in severe cases of long duration poor results have been reported.

**Synergistic Effect of Chlorguanide and Sulfadiazine Against Plasmodium Gallinaceum.**—Greenberg and his co-workers say that sulfadiazine was the first compound proved to be a complete causal prophylactic against Plasmodium gallinaceum in the chick and has been used by many laboratories. Among the few compounds, other than the sulfonamide, found to have prophylactic action against P. gallinaceum is chlorguanide (1-[p-chlorophenyl]-5-isopropylbiguanide). Concurrent administration of chlorguanide and sulfadiazine was examined for prophylactic and suppressive activity against Plasmodium gallinaceum infections in the chick. It was found that the two drugs potentiate each other. The potentiation could not be accounted for by the concentrations of the drugs in the blood. The toxicity of the two drugs in combination was additive.

**Determination of Barbiturates.**—Goldbaum says that a procedure for the determination of thiopental based on its strong ultraviolet absorption spectrums was demonstrated to be highly specific, sensitive and quantitative. The present report is of a procedure that is applicable to the quantitative determination of barbiturates other than thiobarbiturates. The principle of the method is based on the extraction of the drug by an organic solvent and its removal from the organic solvent by extraction with alkali. The concentration of barbiturate in the alkaline solution is determined by the intensity of the absorption in the ultraviolet. For the optical measurements, the Beckman photoelectric quartz spectrophotometer with the standard 10 mm. square quartz absorption cells is used. The author stresses that this is a simple, rapid, highly specific procedure for the determination of barbiturates in blood and tissues, which is based on the characteristic ultraviolet absorption spectrums of the malonyl urea ring structure. The method is sensitive to 0.4 mg. per hundred cubic centimeters of blood and 1.0 mg. per hundred grams of tissue with an error of less than 10 per cent. This procedure is applicable to the clinical, pharmacologic and toxicologic investigation of barbiturates in blood and tissue.

**Bronchial Adenoma.**—Souders and Kingsley say that although bronchial adenoma was first recognized sixty-five years ago, it received little mention until recently. The recent advances in thoracic surgery have broadened the therapeutic approach to these tumors, as well as to other types of pulmonary lesions. The authors review the literature and present their own observations on 15 cases of bronchial adenoma, which were detected among 217 histologically proved primary lung tumors encountered at the Lahey Clinic since 1930. This amounts to an incidence of 6.9 per cent. Adenomas can usually be visualized bronchoscopically, and their characteristic appearance in most cases serves to differentiate them from carcinoma. Bronchial adenoma is a potentially malignant tumor, but the malignancy is of a low grade. Sixty per cent of bronchial adenomas occurred in patients less than 40 years of age. The incidence was slightly greater in female patients. A history of chronic cough, hemoptysis and repeated pulmonary infections, or symptoms of atelectasis, localized wheeze, obstructive emphysema or unilateral bronchiectasis are indications for bronchoscopy on a suspicion of adenoma. Inasmuch as surgical resection removes the infected lung tissue as well as the entire tumor and prevents malignant degeneration, it is the treatment of choice. Local removal may suffice for pedunculated adenomas without extrabronchial entension. The possibility of recurrence necessitates repeated bronchoscopic examinations.

**Chronic Subdural Hematoma: Relief of Hypotension.**—LaLonde and Gardner call attention to the fact that failure of the compressed hemisphere to expand after evacuation of a subdural hematoma is associated with hypotension of cerebrospinal fluid and may be a grave prognostic sign. The symptoms of intracranial hypotension may simulate those of intracranial hypertension. Why the hemisphere fails to expand or why the intracranial pressure remains subnormal is not known, but the authors have found that both conditions respond favorably to the intraspinal injection of isotonic sodium chloride solution. The presence or absence of the hematoma membrane does not affect the syndrome; removal of the membrane is not necessary. Expansion was accomplished by intraspinal injection of saline solution in 5 cases and by intraventricular injection in 2 cases. The volume of fluid introduced at a single injection varied from 50 to 220 cc. In addition to the 7 cases of subdural hematoma in which the compressed hemisphere failed to expand spontaneously, this procedure was employed in 2 cases of intracranial hypotension following operation for other conditions. This series of cases indicates that failure of expansion of the compressed hemisphere is more common in elderly patients who do not have increased intracranial pressure before operation. Expansion of the compressed hemisphere decreases or abolishes the subdural dead space, restores the brain to a more normal anatomic and physiologic state and obviates the need for drainage of the subdural space.

**Steroid Hormones in Diabetes.**—Stoner points out that diabetes mellitus may exist without actual disease of the pancreas and that various hormones are involved in the utilization of carbohydrates. All the steroid hormones used clinically (estrogens, androgens, progestin and the adrenocortical hormones) have been reported to influence carbohydrate metabolism. All these steroids are derivatives of cyclopentenophenanthrene. After briefly discussing their chemistry he reviews the clinical and physiologic data concerning the effects of the various steroid hormones on carbohydrate metabolism. The steroid hormones most used in therapy of diabetes mellitus are the estrogens, the androgens and certain adrenocortical substances. The author shows that with due consideration to their contraindications these steroid hormones are useful adjuncts in the therapy of selected patients, particularly the juvenile and the climacteric diabetic found to be difficult to control with insulin alone.

**Cytologic Smear in Diagnosis of Cancer.**—According to Shushan the cytologic smear has several limitations as a general diagnostic procedure. First, as its name implies, it is applicable only to those regions of the body which produce material from which a smear can be made. Second, diagnoses must be made from the characteristics of desquamated cells and groups of cells without actually seeing the invasion of tissue by these malignant cells. The advantages of the method are numerous: It is simple to obtain material; hospitalization is not necessary, and the smear can be repeated as often as necessary and is therefore excellent for the follow-up of suspected cases. The smear is an excellent method for following cases after operation or radiation. It often detects carcinoma in situ before the appearance of symptoms or lesions, and is often positive before the results of any other test are diagnostic. The author concludes that the cytologic smear is no substitute for older methods of diagnosis. It is a new tool to be used with other procedures in the fight against cancer.

**Epileptic Seizures Confused with Functional Mental Disorders.**—Masland is of the opinion that there has been an unfortunate tendency to consider the mind as separate from the brain. The fallacy of this point of view is most strikingly apparent when one considers those patients whose mental symptoms are found to be closely related to organic brain disease. The author presents 3 cases of epilepsy in which mental symptoms predominated. The first 2 of these patients had been treated for long periods under the belief that their illness was purely functional. The psychic disturbances manifested by these epileptic patients are probably partly due to the disturbance of brain function occasioned by the abnormal epileptic discharge. Closely related to the effects of the seizure itself is the confusion state which develops after the seizure is over, and presumably is a result of fatigue or relative anoxia of the previously active area. On this basis probably depend the confusion states, the periods of amnesia and the occasional postictal furors which are observed in patients with focal lesions. The distinguishing features which serve to indicate the epileptic nature of these mental disturbances are the episodic character of the mental aberration and the occurrence of partial or complete impairment of consciousness. The appearance of generalized seizures in addition to the minor or petit mal type of attack is an additional clue. The diagnosis can usually, but not always, be confirmed either by electroencephalogram or by the response of the patient to therapy with "dilantin" (diphenylhydantoin sodium) and phenobarbital. These patients present a twofold problem lying in the realm of both psychiatry and neurology.

**Treatment of Localized Osteomyelitis.**—Oringer reports 1 case of subacute localized osteomyelitis of the maxilla following the extraction of the upper right cuspid and first molar in a man aged 49 and 1 case of subacute localized osteomyelitis of the mandible following the extraction of the lower four anterior teeth in a man aged 62. In both cases routine postoperative measures were unavailing to check or cure the infection. In the first case treatment attempted by inserting penicillin cones locally into the affected area proved completely ineffective. The prolonged presence of these cones and the progressive deterioration after their insertion would indicate that they may have aggravated the condition by acting as foreign bodies. In the second case the local use of tyrothricin, without accompanying systemic therapy, produced improvement, but failed to effect a cure. In both cases, combined local and systemic chemotherapy by irrigation with tyrothricin, application of gauze dressings prepared with bismuth subnitrate-iodoform-petrolatum paste and by intramuscular administration of a total dose of 1,200,000 units of penicillin, was highly effective. Although the amount of surgical intervention required in both cases was minimal, it was essential. Suppuration was diminished shortly after chemotherapy was instituted, but it was not until the sequestrums were removed that suppuration ceased entirely and a cure was effected. In both cases the infection was successfully confined to the limits of the original areas of involvement, the fever and malaise were rapidly overcome, and shortly after active infection was checked, evidence of rapid bone regeneration was noted. Chemotherapy provides sterilization of the infection. Evacuation of the contents of the diseased area, both pus and sequestrums, by means of surgery must then be performed before obliteration of the resultant cavity by bone and tissue regeneration can take place.

**Actinomycosis.**—According to Robinson and his co-workers, studies of actinomycosis have been misleading, chiefly because of misunderstandings concerning the etiologic agent. Actinomyces israeli, the causative organism, is an anaerobic or microaerophilic organism which does not exist free in nature but which has been confused with the aerobic forms of actinomycetes occurring on grasses and grains. A. israeli is a normal inhabitant of the oral cavity, and more than 50 per cent of actinomycotic lesions are of the cervicofacial type. Clinically, actinomycosis may occur in many different forms varying from incipient lesions that are not suspected until biopsy reveals the presence of A. israeli to extensive, disfiguring, proliferating lesions. The absence of the so-called sulfur granules from the pus should never be taken as positive evidence that actinomycosis does not exist. Conversely, small masses of bacteria, food debris, bone spicules, cell debris or other foreign matter in pus may appear macroscopically similar to "sulfur granules" in the absence of actinomycosis. Culture methods are more reliable than examination of direct smears. The biopsy is of value in diagnosis of actinomycosis because of the rather characteristic appearance of the colonies of A. israeli within tissue lesions. Along the peripheries of circular masses and along the borders of trabecular plaques farthest from the bone, acidophilic clubs and ends of filaments may be seen projecting; they give the ray appearance to the granular colonies. Since A. israeli may form colonies without clubs and since similar granules may be observed in actinobacillosis, the finding of characteristic granules in the tissue is not evidence per se of actinomycosis, but is of relatively high diagnostic value.

**Inflammatory Carcinoma of Breast.**—Meyer and his associates call attention to the fact that certain malignant lesions of the breast may simulate inflammatory lesions, for which they have been mistaken, although they represent a highly virulent type of cancer. They reviewed 7,000 consecutive cases of malignant lesions of the breast encountered at the Mayo Clinic. Cases in which inflammatory signs were manifested were selected for further study. After the discarding of cases in which redness and edema were localized and obviously due to early necrosis and infection from invasion of the skin, 74 cases which seemed characteristic were selected. Tissues obtained in 65 of these cases were studied. The fact that 74 cases of the inflammatory type of cancer were discovered among 7,000 cases of mammary cancer indicates an incidence of about 1 per cent. The disease was found to occur in the same general age group as carcinoma of the breast, and there was no correlation with pregnancy or lactation. The incidence of bilateral cancer was two times that noted in comparable cases of the usual carcinoma of the breast. The left breast was affected primarily nearly twice as frequently as the right. The skin over the breasts was red or edematous or both, and palpation frequently revealed diffuse infiltration. The axillary nodes were involved in all cases. The lesions were diffuse, high grade adenocarcinomas, which frequently involved the lymphatics and occasionally the blood vessels. Characteristically, the cancer spread through the subepidermal lymphatics. There was no evidence of bacterial infection, and ulceration of the skin was rare. The inflammatory appearance was apparently due to blockage of the lymphatics by cancer cells and the resultant vascular phenomena. Prognosis for life is poor, but 3 patients lived more than five years after operation, and 1 was alive nine years after operation.

**Treatment of Acute Renal Insufficiency.**—According to Muirhead and Hill different conditions are associated with acute bilateral renal damage and acute renal insufficiency. The syndrome resulting from this type of renal lesions has been designated by different terms such as "renal anoxia syndrome," "lower nephron nephrosis" and "hemoglobinuric nephrosis." The high mortality rate of certain types of acute renal insufficiency may be substantially lowered by altering the therapeutic approach. The authors report 3 cases to lend additional support to this thesis. The proposed management consists of positive measures based on renal morphologic changes and the main features of the clinical course. There are three main phases, each of which requires its own therapeutic measures. The hypotension of the first phase is best managed with completely compatible blood. During the second phase (renal insufficiency) a near normal state of hydration is maintained and complete starvation and definite acidosis are prevented as much as possible. During the third phase (diuresis) not only is the water loss replaced but as much as possible a gram for gram salt replacement is made. The regimen is based on the premise that damaged kidneys require time for healing. Evidences of healing appear between the eighth and the twelfth day. Attempts to stimulate the kidneys to produce urine during the oliguric period usually fail. An excessive intake of water or salts over that immediately lost causes an overload and upsets existing osmolar concentrations. It is believed that much of the mental aberrations can be attributed to these complications. Relatively mild forms of this condition may be made severe or even fatal as a result of complications related to management.

**Gastric Motility and Effect of Drugs on Motility Following Complete Vagotomy.**—Stein and his co-workers studied the gastric motility of 27 patients with peptic ulcer before and after vagus section. They found that no spontaneous or insulin-induced type I, II or III hunger contractions are present in the fundus of the stomach up to nine months after complete vagotomy. There is great delay in gastric emptying following complete vagotomy. After incomplete vagus section, hunger contractions are present either spontaneously or following insulin hypoglycemia. "Doryl" (carbaminoylcholine) 0.25 mg. subcutaneously, or "urecholine" (carbaminoyl-beta-methylcholine chloride), 5.0 mg. subcutaneously, produced a rapid but transitory increase in gastric tone and motility following complete vagotomy. The oral administration of "doryl," 2.0 to 4.0 mg., or "urecholine," 10.0 mg., usually produces a more sustained increase in gastric tone and motility. Neostigmine bromide and methacholine chloride have little if any effect on gastric motility after complete vagotomy.

**Serum Proteins in Pregnancy.**—Worsham studied the relationship of edema of pregnancy to the serum protein level of the blood under controlled conditions of a relative maximum of meat intake. A group of 184 cases studied during food rationing was compared with 193 cases studied after food rationing was discontinued. No difference in blood serum protein levels was found. Only 52 per cent of an average group of American women had a total serum protein level that could be considered within normal limits. Nineteen per cent had bodies dangerously depleted of proteins and were not good candidates to bear large families of strong, healthy children. After elimination of all controllable factors, 8 per cent of the normal protein group had some edema, usually mild; 78.4 per cent of the group frankly deficient in protein had edema and a large percentage of these women had severe swelling. After eliminating as an error the 8 per cent in the "normal" serum protein group showing edema and adjusting for this error in the other groups, patients with serum proteins between 6.0 Gm. and 5.5 Gm. per hundred cubic centimeters of blood showed 21.2 per cent edema, and the group with serum protein levels of 5.5 Gm. and below showed 72.3 per cent edema. Hemoglobin determinations were found to fall with the serum protein level. Hematocrit determinations and red blood cell counts did not seem noticeably affected.

**Importance of Leprosy in Orthopedic Surgery.**—Metcalfe considers it probable that increased numbers of sporadic cases of leprosy may appear in the temperate zones as the result of mass migrations of troops and families through endemic areas during the war period. Certain symptoms of leprosy simulate orthopedic lesions and so the patient with beginning leprosy may appear at the orthopedic clinic for diagnosis. The author describes some of the lesions, particularly those involving the bones and joints. Roentgenologic findings on fingers and toes include notching of tip, sliced off appearance, collar button absorption of short phalanges and enlarged nutrient foramen. Joint lesions include: subchondral cysts, degenerative changes, ankylosis and subluxation. Among the larger lesions the author mentions: (1) transverse linear zone of rarefaction at phalangeal epiphysis as a sign of leprous osteochondritis; (2) cystic degeneration near nutrient artery of phalanx as sign of a leprous osteomyelitis; (3) concentric bone atrophy with narrowing of shaft without rarefaction, and (4) absorption of distal articulating surface of bone with "awl-shaped" appearance, also likened to that of a "sucked candy stick." The author shows that diagnosis of leprosy must include a wide variety of dermatologic, neurologic and other conditions. The specific diagnosis depends on the demonstration of the Hansen bacillus, which is best done by making a small oblique incision in the skin at the border of the pigmented or anesthetic area with a razor blade and scraping a drop or two of serum for acid-fast staining.

**Industrial Medicine Comes of Age.**—Felton shows that wartime development in industrial health methodologies have allowed extension of preventive medicine procedures into the peacetime production scene. Through selective placement, workers are matched against jobs, allowing employment of nearly 100 per cent of applicants. Case-finding surveys have been developed in industry in order to detect tuberculosis, syphilis, early heart changes and alterations in visual and aural skills. Understanding of the human relations involved in the group living of industry has led to resolution by the medical director of situational conflicts, providing management with a better method of reversing impaired employee relations. The introduction of rehabilitation procedures, through the cooperation of industry and the Office of Vocational Rehabilitation, has made for job betterment of the physically limited employee. Industrial medicine has given further evidence of coming of age by the creation of a specialized literature, the establishment of criteria for fellowships and residencies and the formation of professional organizations.

**Rapid Digitalization.**—The present clinical trial by Evans and his associates was designed to discover the most effective preparation for rapid digitalization when given orally or intravenously, by comparing the effect of as many preparations as possible in the same patient and under the same conditions. The following drugs were tested: strophanthin, ouabain and k-strophanthosid, digoxin, digitoxin, lanatoside C, digitalis leaf, and the tincture of digitalis. A clinical trial was made on 20 patients with auricular fibrillation and heart failure. Digoxin and lanatoside C proved to be the best and digitoxin was scarcely less efficient. Should it be necessary to induce digitalization within two hours, digoxin as 1.5 mg. intravenously or as 2 to 3 mg. orally, and lanatoside as 1.5 mg. intravenously only, can best accomplish it. To establish adequate digitalization within four hours digoxin, 2 mg. by mouth, is an effective method. As it is seldom necessary to obtain a digitalis effect in less than two to three hours, and as intravenous medication may be less convenient, digoxin, 2 to 3 mg. by mouth, is generally the best way to induce rapid digitalization.

**Rat Bite Fever.**—Lominski and his associates point out that infection with Spirillum minus (originally named Spirocheta morsus muris by its Japanese discoverers in 1916-1917) is the commoner variety. Infection with Streptobacillus moniliformis is much rarer. The incubation period of the spirillar infection is usually longer (seven days or much more) than in the streptobacillary disease (three days or more), but the period is so variable that only a clear history of a bite followed by a long interval before illness develops might clinically suggest the spirillar variety. The newer arsenical drugs are effective against the Spirillum minus, but the streptobacillary disease ran a protracted and serious course until the advent of penicillin. The authors report the case of a man who was bitten on the right thumb while handling a hooded rat prior to an experimental operation. On the morning of the third day he felt ill on wakening. A severe rigor followed almost immediately, lasting half an hour. Treatment with penicillin was completely successful, the disease being cured. Much larger dosage, probably excessive, was employed than in cases previously described, but the illness was severe and relapse had *occurred in the days of penicillin scarcity.*

**Postprandial Symptoms Following Partial Gastrectomy.** —Irvine reviews observations on 24 patients in whom postprandial symptoms developed after they had undergone subtotal gastrectomy for duodenal or gastric ulcer. The type of operation performed was a gastrectomy, three quarters of the stomach and the first inch of the duodenum being removed, with an antecolic anastomosis. The patients complained of heaviness and fulness in the epigastrium, accompanied by muscular or body fatigue; in cases with more severe effects they may have to lie down and may fall asleep. A flushing of the skin may occur and the patient may perspire. Giddiness and palpitations occur often. Such symptoms were present in all 24 cases. Bilious vomiting occurred in 2 of the cases. The symptoms started either while the patient was in the hospital or as soon as he went home. The symptoms started almost immediately after meals or while the patient was still eating. The upset usually lasted twenty to thirty minutes. The rapidity of onset suggested a mechanical causation, and in nearly every case the symptoms could be brought on rapidly by eating more quickly, and when a larger meal was given the symptoms usually increased in severity. A careful study was made of the type of food and the amount taken at each meal in the day, and a rough measure of the total bulk of each meal and its total carbohydrate content was made. In 23 cases the symptoms appeared only after "the big meal," i. e., the most bulky meal of the day. By tests with dextrose it was proved that it was the bulk and not the carbohydrate content of the meal which mattered. The author cites factors which indicate that the symptoms are due to mechanical distension of the intestine and the resulting stimulation of the sympathetic system.

**Relation of Vitamin A to White Blood Cell Count.**—Hassan and his associates studied the blood of 60 normal male students to determine the relationship between the vitamin A content of the blood and the total and differential leukocyte count. They found that with the increase in the vitamin A content the total number of leukocytes tends to decrease. Lymphocytes and monocytes tend to increase and neutrophils and eosinophils decrease. There is a shift to the right in the hemograms of Arneth and Schilling. Vitamin A deficiency brings about physiologic leukocytosis. It appears that there is some relationship between vitamin A and the general defense mechanisms of the body.

Acute Transverse Myelitis Complicating Pneumonia: Report of Case. A. I. Suchett-Kaye.—p. 417.

**Primary Tuberculosis with Bacilli in Spinal Fluid.**—Choremis and Vrachnos present histories of 2 children, boys of 11 months and 2 years, respectively, in whom tubercle bacilli were isolated from the cerebrospinal fluid without accompanying manifestations of tuberculous meningitis. Both patients, 1 of whom received streptomycin, survived, and they were well four and two and one-half months later. In the cerebrospinal fluid tubercle bacilli may sometimes either exist without any focal lesion in the brain or meninges, or may derive from a minimal meningeal lesion which resolves. The second explanation seems the more likely. It is suggested that in assessing "cure" of tuberculous meningitis greater weight should be attached to chemical and cytologic findings in the cerebrospinal fluid than to the results of culture for the tubercle bacillus.

Leontiasis Ossium. C. B. Way.—p. 457.

**Streptomycin in Pulmonary Tuberculosis.**—Keers says that through the American Red Cross a consignment of 600 Gm. of streptomycin was presented to a Scottish sanatorium. The cases selected for treatment were (1) a case of severe tracheobronchial tuberculosis, (2) a tuberculous sinus in the chest wall persisting after a thoracoplasty for tuberculous empyema, (3) 2 cases of acute exudative pulmonary tuberculosis and (4) a small contralateral spread of disease following thoracoplasty. The remaining streptomycin was used as a cover during the stages of thoracoplasty operations in cases in which there seemed to be an appreciable risk of extension of the disease. All patients received 1 Gm. of streptomycin in twenty-four hours, given in two doses of 0.5 Gm. at 8 a. m. and 8 p. m. Administration was by intramuscular injection. The response of the bronchial disease, the chest wall sinus and the laryngeal lesion was prompt and unmistakable. This suggests that streptomycin will find its greatest sphere of usefulness in the management of the extrapulmonary sequelae of tuberculosis. Case 4, an active pulmonary lesion of exudative type, was disappointing. It had been hoped to control the exudative phase and render the patient fit for thoracoplasty; this was not accomplished. In the case of tuberculous pneumonia, on the other hand, there appeared to be appreciable benefit and the fever and constitutional symptoms subsided early conforming to the experience of Allison. The part played by the streptomycin in case 6 and in the 4 thoracoplasty cases in which it was used prophylactically is impossible to assess. The decision to use streptomycin in pulmonary tuberculosis should be taken only after careful consideration. The benefit to the patient is by no means certain, and this possible benefit must be weighed against the danger of producing a streptomycin-resistant strain of bacilli and thus creating a future public health problem. On the available evidence there appear to be few cases of purely pulmonary disease in which the use of streptomycin could be advised. It may have value in treatment of the extrapulmonary complications of pulmonary tuberculosis. Its use in tuberculous pneumonia, to prepare the way for effective collapse therapy, is probably justified.

**Human Meningoencephalitis Due to Louping Ill Virus.**—Davison and Neubauer point out that louping ill occurs naturally in sheep and has been traced to a filter-passing virus for which the sheep tick (Ixodes ricinus) is the natural vector. All 6 previously reported cases of louping ill in human subjects have been in laboratory workers. The authors cite histories of 2 patients with louping ill in whom there was evidence that the disease had been contracted naturally. The clinical picture of louping ill in man is that of meningoencephalitis, usually following a prodromal influenza-like illness and followed by complete recovery in most cases. It is suggested that the illness would be more often diagnosed if it were suspected whenever meningoencephalitis appears in a person exposed to louping ill virus. The authors present evidence linking louping ill with Russian spring-summer encephalitis.

Relaxing Agents in Anesthesia: Brief Appraisal. S. V. Marshall. —p. 150.

**The Coombs Test for Isosensitization of the Newborn.**—Jakobowicz and her associates state that Coombs and others in 1945 described a new method of testing for "incomplete" Rh antibodies (Wiener's "blocking" antibodies) and for weak Rh agglutinins. They had found that rabbit antihuman globulin serum would agglutinate red blood cells which had adsorbed Rh antibodies onto their surface. It was thought that the rabbit antihuman serum reacted with the globulin part of the adsorbed antibodies. The test can be applied as the "direct Coombs test" and the "indirect Coombs test." In the direct test cells suspected of having been sensitized are exposed to the action of immune rabbit serum, which will agglutinate them if they have previously adsorbed antibody. In the indirect test a serum suspected of containing antibody is mixed with normal cells, which are subsequently tested with the immune rabbit serum. Although the direct test is primarily used in investigations for Rh sensitization, it is not specific for Rh antibodies, and a positive reaction simply indicates sensitization of the red cells by an antibody capable of reacting with the rabbit antihuman serum. The indirect Coombs test is used to detect Rh antibodies in the serum of the mother or in the newborn baby. Jakobowicz and her co-workers describe the results of the direct Coombs test on 1,580 specimens of cord blood and of the indirect Coombs test on 48 specimens of maternal serum and of 9 of cord serum. The direct Coombs test appears to be slightly more sensitive than other methods of detecting Rh immunization, although occasional positive reactions are observed in the absence of evidence of immunization. The indirect Coombs test is useful in confirming the presence of small concentrations of antibodies in the maternal or in the infant's serum.

Injuries Produced by Tropical "Water-Beetles." K. V. Earle.—p. 101.

**New Antibilharzial Drug.**—Watson and his co-workers review the history of attempts to develop a drug for the oral treatment of bilharzial disease in human beings and give an account of the development of the new antibilharzial drug "miracil D" ("nilodin"), which is a thioxanthone derivative (1-methyl-4-diethylamino-ethylaminothioxanthone hydrochloride). In those animals to which a sufficient dosage was given over a sufficient length of time, both viable ova and the symptoms of the disease disappeared and at necropsy only dead and disintegrating worms were found. In lower dosages the drug killed some of the worms and cured some animals, but not others. In human beings with bilharzial disease, low dosages appeared to be erratic in action, curing some patients and failing to cure others, but the results of the later trials, in which higher and more frequent doses were given, were more consistent. Viable ova disappeared from the urine or feces, hematuria vanished and the physical condition of the patient substantially improved, but most cases later showed partial relapse. Further improvement was achieved after second treatment, and although few complete cures were obtained the reduction in the number of ova and the amount of blood in urine or feces was considerable. The minimum effective dosage seemed to be 5 mg. per kilogram every twelve hours for a minimum period of five days, although a higher rate is almost certainly desirable. Toxic symptoms are generally slight and appear to affect only 1 out of 5 or 6 patients.

**Ferment Production of Tonsils.**—Šercer and Ruždić cite investigators who studied the metabolism of the tonsils and reason that if ferments are formed in the tonsils, which supposedly play a part in the defense against noxious invaders, these ferments should be demonstrable in the blood stream. In order to throw light on this problem the authors studied the blood of patients for its content in ferments before and after tonsillectomy. They gained the impression that normal or hypertrophic tonsils produce such an amount of sugar-splitting ferments that this fact can be demonstrated in the blood by means of sufficiently sensitive methods. The extirpation of hypertrophic tonsils is followed by a considerable reduction in these ferments, but this condition is compensated after seven to eight days. In the presence of chronic inflammation of the tonsils complicated by systemic diseases the diastatic ferments are present in the blood in reduced or normal quantities and there is no change after the operation. This seems to signify that diseased tonsils produce either no ferments or only minimal amounts. Cases which are exceptions to this rule seem to indicate that the greatly enlarged tonsils had still an adequate amount of functioning tissue. The authors conclude that normal tonsillar tissue plays an essential part in the production of sugar-splitting ferments. They are making further investigations to determine the role of the tonsils in the formation of ferments that split fats and proteins.

*Penicillin in Gonorrhea in Infants and Children. Ambulatory Treatment with Injectable Penicillin (Comparison of Results with Those from Oral Administration). A. Wiederhold and A. Méndez.—p. 335.

**Penicillin in Gonorrhea in Children.**—Wiederhold and Méndez administered penicillin to two groups of infants and children, of 25 children each, with gonorrhea. Most of the children were girls. Children in the first group received penicillin by mouth in a total dose which varied from 200,000 to 1,500,000 units, the children in the second group receiving the drug by intramuscular injection in oil in one dose which varied from 200,000 to 250,000 units. The patients were observed for two years after clinical and bacteriologic recovery. Tests for reactivation of the disease were performed during this period. Permanent clinical and bacteriologic cure was obtained in all patients who received penicillin by mouth. Permanent clinical and bacteriologic cure was also obtained in 20 of 25 patients who had injections and in 5 patients in this group who had penicillin by mouth after failure of penicillin injections. The authors believe that administration of penicillin by mouth is more practical, is painless and more efficient than penicillin by injections.

Present State of Treatment of Burns and Stenoses of the Esophagus; Therapeutic Results. J. Rebattu and H. Martin.—p. 643.
*Peripheral Laryngeal Paralysis, a Complication of Collapse Therapy. Piaget and Seguin.—p. 657.
*Labyrinthine Disturbances Caused by Streptomycin. Moindrot, J. Gaillard and Charles.—p. 667.

**Peripheral Laryngeal Paralysis in Tuberculosis.**—Piaget and Seguin report 4,779 patients with pulmonary tuberculosis who were treated at an altitude sanatorium in the Rhone district of France. Only 12 of these patients presented laryngeal paralysis, which occurred spontaneously in 9 and followed collapse therapy in 3, 2 of whom were subjected to Jacobaeus operation and 1 to phrenectomy. These 2 patients were the only ones of 1,340 on whom pneumolysis was performed, and the third patient was the only one of 170 with phrenectomies. Four additional cases are reported in which laryngeal paralysis occurred after pneumolysis and after surgical pneumothorax respectively. In spite of considerable improvement in surgical technic, the collapse therapy may be complicated by lesions of the laryngeal motor nerve cells. Although the incidence of this postoperative accident is low, it represented one quarter of the total number of cases of laryngeal paralysis which occurred in the patients with pulmonary tuberculosis in this medicosurgical sanatorium. The spontaneous interruption of laryngeal motor function in patients with pulmonary tuberculosis resulted from changes in the mediastinal cellular tissue caused by tuberculous periadenitis, and in rare cases from lesions of isolated peripleuritis. The pathogenesis of the postoperative laryngeal paralysis is related to that of the spontaneous paralysis, but its mechanism is obscure. Anatomic anomalies, exaggerated electric or caloric reactions and a specific fragility of certain nerves which have been sensitized by the bacillary toxin may play their part. Treatment failed except for 1 case, in which recovery was obtained by infiltration of the corresponding sympathetic ganglion. There were no complications besides vocal embarrassment and breathlessness during the first few days. The bronchopulmonary condition was not aggravated in any of the authors' cases.

**Labyrinthine Disturbances Due to Streptomycin.**—Moindrot and his co-workers report the occurrence of vestibular and cochlear disturbances in 16 children and in 34 adults who were treated with streptomycin. The daily dose of the drug varied from 0.25 Gm. to 3 Gm.; treatment was continued for twelve days to eight months. Vertigo appeared in 17 of the 34 adults about the twentieth day of the treatment; instability, mild nausea and a rotatory sensation occurred, but no vomiting. These symptoms disappeared within two to three weeks in spite of the continuation of the treatment. Spontaneous nystagmus occurred in only 3 patients; it was unilateral in 2 and bilateral in 1. Romberg's test was performed on 26 patients and revealed a mild tendency to falling in only 4. Rather frequently the patients could not maintain their equilibrium when standing on one leg. Deafness developed in 4 patients with tuberculous meningitis; it seemed to be the result of the disease rather than of the drug. There was no relationship between the dose of the drug given and the intensity of the disturbance. Three patients presented a total lack of response after 43 Gm., 19 Gm. and 20 Gm. respectively. Another patient presented simple hypoexcitability after 171 Gm. of the drug. One of 2 nurses with vertigo examined by labyrinth function tests showed a pronounced hypoexcitability, while the other presented loss of excitability; neither of them received streptomycin, but both handled the drug with ordinary precautions. Patients examined two to four months after the discontinuation of the treatment showed the same degree of hypoexcitability which was observed in other patients in the course of the treatment. Vestibular recuperation, when it occurs, is slow. In spite of the persistence of the vestibular dysfunction the disturbance of the equilibrium subsided in the great majority of the patients. It is suggested that the toxic effect of the streptomycin is exerted on the central vestibular nuclei. Vestibular dysfunction seems to depend on the individual susceptibility of the patient.

Pancreatolithiasis. L. Abramson.—p. 1506.
Nicotinamide Treatment in Pellagrous Diarrhea ("Pellagra sine Pellagra"). A. Flachs.—p. 1507.

**Analysis of Fatal Cases of Bleeding Peptic Ulcer Treated with Free Feeding.**—Meulengracht states that in Bispebjerg Hospital's Medical Division B free feeding has been the routine treatment of peptic ulcer since 1931. Of the 1,031 patients treated, with average age of 48, 26 died during hospitalization, 19 from persistent or repeated hemorrhage. Of the 26, 25 were over 40 and half were over 60. In all the fatal cases the bleeding was manifested by hematemesis. Many patients were too weak to eat and drink. The gross mortality was 2.6 per cent; excluding cases in which death was due or largely due to complicating disorders and cases fatal within twenty-four hours, the net mortality was 1.5 per cent. The author concludes that more extensive use should be made of blood transfusions, primarily in patients over 40 with hematemesis and clinical signs of persistent or repeated hemorrhage. Operation should be considered only in the case of patients over 40 when the condition is threatening in spite of repeated blood transfusions, if no grave contraindications for operation exist and the ulcer has been demonstrated roentgenologically.

**Treatment of Achalasia Cardiae (So-Called Cardiospasm) with Forced Dilation.**—Achalasia cardiae, Gjertz says, designates a condition in which the passage of food from the esophagus to the stomach is hindered by functional disturbance in the cardiac region with more or less dilatation of the esophagus above the cardia. Most of his 67 patients had been previously treated with spasmolytics without effect, and in a few cases operation had been done with no or transient effect. Forced dilation was carried out in 64 patients with good results in most cases. Follow-up of 45 patients from half a year to seven years showed that 30 were completely or almost completely well; 14 improved, and 1 not improved. Only 6 patients felt that the remaining symptoms affected their general condition and ability to work. Hurst's view that no true spasm is associated with achalasia cardiae seems to be supported. Cases with true spasm in the cardia region were eventually found to be cases of cancer of the cardia or adjacent parts of the stomach.

*Bronchiectasis, A Surgical Disorder. A. P. Naef.—p. 639.
Tyrothricin, A New Antibiotic for Local Treatment in Otorhinolaryngology. M. Mirault-Kretchmar.—p. 647.

**Surgical Treatment of Bronchiectasis.**—Naef treated 3 adults and 1 child with bronchiectasis, by surgery. In case 1 a lobectomy of the lower lobe of the left lung and a resection of the lingular segment was performed on a man aged 43 under unfavorable conditions because of a chronic hemopneumothorax which became infected during the operation and which required a secondary plastic operation. Except for this almost unavoidable accident the result was satisfactory, and the patient, who before the operation had been an invalid, has resumed his work. In case 2, the 22 year old patient made a complete recovery after a lobectomy (lower lobe, left lung) for localized bronchiectasis. In case 3 excision of the lower and median lobes of the right lung was performed on a man aged 53 for advanced chronic bronchiectasis of twenty-five years' duration. The clinical and functional result was satisfactory. In the fourth patient, a boy aged 6, atelectasis of the left lung developed after aspiration of a foreign body, resulting in multiple pulmonary abscesses and bronchiectasis. A left pneumonectomy was well tolerated, and the child recovered from grave bronchopulmonary suppuration. The preoperative and postoperative administration of antibiotics by the intramuscular route and in the form of aerosols has improved the surgical results. Penicillin and streptomycin therapy combined with postural drainage and bronchoscopic aspirations reduced the risk of atelectasis and of postoperative pneumonia resulting from bronchogenic dissemination of secretions. The technic of multiple segmental resection makes possible effective treatment of multifocal and bilateral bronchiectasis with conservation of normal pulmonary tissue essential for respiratory function. In young patients, and particularly in children, a genuine vicarious hypertrophy of the remaining healthy pulmonary tissue is possible, while in adults emphysema may be the sequel of resection. Early diagnosis of bronchiectasis makes surgical treatment feasible at the most favorable time, i.e., during youth.

*New Method of Graphic Registration of Certain Mechanisms of Cardiovascular System as Based in Variation of Electrolytic Resistance. B. Günther and G. Concha.—p. 59.

**Graphic Registration of Certain Mechanics of Cardiovascular System.**—Günther and Concha describe a new method for the registration of the venous, radial and carotid pulse, the apex beat and the peak of the R wave of the electrocardiogram, in man. The method consists in the utilization of a variable electrolytic resistance, the value of which is modified by the movements of a fine wire immersed in a capillary tube containing alcohol and glycerol. A direct current flows through the wire. The potential differences thus created are of the order of millivolts and are amplified by means of any common electrocardiograph. The details of the electrical circuit and of the different recording capsules are specified.

*Bouillaud's Disease and Treatment of Its Forms of Slow Course by Intra-Arterial Injection of Strepto-Enterococcic Anavaccine. M. Debray and Miss M. Provendier.—p. 2325.
Familial Neutropenia. J. Bousser and R. Nedey.—p. 2332.
Practical Conceptions of Electrocardiography. P. Bardin and G. Mayonade.—p. 2336.

**Bouillaud's Disease.**—According to Debray and Provendier, clinical facts, anatomic observations and infectious complications of rheumatic fever suggest that it is a disease of the arterial tree. The insidious latent course or the more or less delayed bouts of this disease strongly suggest the persistence of a specific germ. The latter may cause or may maintain or renew under certain influences a state of sensibilization which may explain the nature of the attacks. It is also possible that fatigue, cold or an infectious episode may be sufficient to elicit an acute attack similar to that which may be produced by injection of vaccine or serum. Although the salicylates are considered specific in the treatment of acute forms of rheumatism, there are many cases in which arthralgia, fever or cardiac disturbances persist. In these cases of a slow course which are refractory to chemotherapy, favorable results were obtained with intra-arterial injections of an anavaccine, 1 cc. of which contained 0.4 cc. of a lysate of streptococcus and enterococcus digested with formaldehyde and 0.2 cc. of a sodium lysate of staphylococcus. Twelve patients, 9 women and 3 men between the ages of 20 and 61 years, were given anavaccine injections in the femoral artery every four to seven days. The initial dose of 0.25 cc. was increased progressively with 0.25 cc., provided that the resulting rise of temperature did not exceed 38.5 C. (101.8 F.). The temporary rise of temperature after the injection was occasionally preceded by a sensation of cold in the fingers and toes and paleness of these parts. No serious accidents occurred. Salicylates and anavaccine do not exclude one another but may be used combined successively or separately. One compensates for the weakness of the other. The anavaccine should not be employed in patients of advanced age or in those with arterial hypertension or renal insufficiency. It is recommended for cases with a prolonged course or recurrences and for cases of torpid cardiac disease with bouts of myocardial failure.

# Book Notices

**A-B-C's of Sulfonamide and Antibiotic Therapy.** By Perrin H. Long, M.D., F.R.C.P., Professor of Preventive Medicine, the Johns Hopkins University School of Medicine, Baltimore, Md. Cloth. Price, $3.50. Pp. 231. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London W.C. 2, 1948.

One of the most rapidly changing fields of medical practice is concerned with the use of sulfonamide drugs and antibiotics. While it was only a little over ten years ago that the first sulfonamide compound was introduced into medical practice in this country, this class of agents has received such wide acceptance that many persons seem to accept them more or less casually, as if they had been in existence for a lifetime. Thousands of compounds have been developed, but only a few have been found practical for introduction into medical practice. Nevertheless, these few have provoked practically untold wonders in the art of preventing and treating disease. Their status, however, does not remain static and almost overnight new claims are offered or old ones disputed. The same is true of the antibiotics. Not long ago penicillin was in such short supply that the medical profession was practically begging for the material; now it is plentiful. But in the meantime other antibiotics have made their appearance; for example, streptomycin, "chloromycetin," aureomycin and "polymyxin." Unless some means is provided for making available pertinent information in easily accessible form, existing confusion may be perpetuated. The book "A-B-C's of Sulfonamide and Antibiotic Therapy" provides a means for minimizing such confusion for the student and practitioner. It is a handy volume containing a wealth of material offered in a readable style and with a minimum of diverting generalizations. The book offers discussions on dosage of sulfonamide drugs and antibiotics according to their method of administration and other pertinent points that must be kept in mind by the prescriber, such as the possibility of drug resistance and the preparation of sulfonamide or antibiotic solutions for parenteral administration. In addition, the book provides a discussion of the clinical applications of sulfonamide compounds and antibiotic therapy in various diseases and conditions ranging from abscess to yaws. The author is to be commended for his practical presentation, and the student and practitioner would be well advised to have this handy little volume always accessible.

**Personal and Community Health.** By C. E. Turner, A.M., Ed.M., D.Sc. Eighth edition. Cloth. Price, $4. Pp. 565, with illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3. 1948.

This is a new edition, the eighth, of a book first published in 1925 which has become a standard college textbook of hygiene. The book is characterized by a comprehensive scope and complete treatment of its various topics. The chapters of Part I, on the health of the individual, deal respectively with hygiene and health, nutrition, digestion, oral hygiene, respiration, circulation, the kidneys, the skin, endocrines, the sense organs, hygiene of the nervous system, mental hygiene, narcotics and stimulants, the hygiene of body activity, body mechanics, foot hygiene, heredity and health, the hygiene of reproduction, and adult hygiene. It is a combined treatise on anatomy, physiology and hygiene, with practical sidelights, such as the use of blood plasma and how to take a sun bath without overdoing it.

Part II deals with community health, with chapters on the science of disease prevention; essential facts of immunity; alimentary and respiratory infections; contact and inoculation diseases; food control; water supply; waste disposal; ventilation, heating and lighting; public health administration; maternal and child hygiene; school hygiene, and industrial hygiene.

There are three appendixes dealing respectively with the details of the control of communicable diseases, with disinfection and disinfectants, and with prefixes, suffixes and combining forms. There are an excellent glossary and a good index.

The book is profusely illustrated with photographs, drawings and diagrams on almost every page. Always a standard textbook characterized by accuracy and reliability, this eighth edition surpasses previous editions in readability and in attractiveness. The latter is due largely to the illustrations, to an easy to read type face and good semigloss book paper. Each chapter has an extensive list of references.

**Bailey's Text-Book of Histology.** Revised by Philip E. Smith, Ph.D., Professor of Anatomy, College of Physicians and Surgeons, Columbia University, New York, and Wilfred M. Copenhaver, Ph.D., Associate Professor of Anatomy, College of Physicians and Surgeons, Columbia University. Twelfth edition. Cloth. Price, $7. Pp. 781, with 455 illustrations. Williams & Wilkins Co., Mt Royal & Guilford Aves., Baltimore 2, 1948.

This standard text shows the results of careful revision. Although the changes from the previous edition are considerable and inclusive of much new information, the original plan and mode of presentation are unchanged. It is intended for elementary students of medicine and dentistry but contains enough material to be useful for later years of the medical and dental curriculum. A commendable and reasonably successful attempt is made to integrate histology with border subjects such as gross morphology, embryology and physiology, but the book retains its essential character as a well written treatise of normal histology. Illustrations are numerous and mostly of excellent quality. Selected references are appended to each chapter. Although some of the older type face and cuts show considerable evidence of wear, the production of this book is of excellent quality. Its contents are recommended as rating with the best in the field.

**Pharmacology.** By J. H. Gaddum, Sc.D., F.R.S., M.R.C.S., Professor of Pharmacology in the University of Edinburgh, Edinburgh. Oxford Medical Publications. Third edition. Fabrikoid. Price, $8. Pp. 504, with 75 illustrations. Oxford University Press, 114 Fifth Ave., New York 11; Amen House, Warwick Sq., London E.C. 4, 1948.

Since its first revision this book has undergone a number of changes that have generally increased its usefulness. However, like others so commonly encountered today, it presents with too little criticism some views that may be currently popular but not supported by adequate evidence. For example, in the discussion of vtiamin E there is the statement:

"It has been shown to be essential for reproduction in rats, mice, rabbits, and hens. It is not definitely known whether other animals can suffer from deficiency of tocopherol, but favourable reports have been published on the use of wheat-germ oil to cure habitual abortion in women, sheep, cows, and pigs. It has been suggested that it might be used in the treatment of various diseases of muscles and nerves."

What is lacking is a statement to the effect that such claims have not been sufficiently substantiated for the medical profession to apply vitamin E therapy generally for these conditions. Since the book was written in the United Kingdom, it is not surprising to find thiamine hydrochloride referred to as "aneurine hydrochloride," which is British Pharmacopia terminology. Unfortunately, such British terminology is not always familiar to all students in the United States. With the rapid advancement of drug therapy it is necessary to have available as much information as can be gathered, and every book that contributes something to this information may be helpful to some one. The present book will unquestionably be read by the teacher and more searching students with this view in mind. However, it is not the type of book that can be recommended for medical students in American medical schools. It would, nevertheless, have a useful place in the libraries of medical schools and teachers, for those who might wish to make reference to it.

**Understandable Psychiatry..** By Leland E. Hinsie, M.D., Professor of Psychiatry, College of Physicians and Surgeons, Columbia University, New York. Cloth. Price, $1.50. Pp. 359. The MacMillan Company, 60 Fifth Ave., New York 11, 1948.

Dr. Hinsie has addressed his book, "Understandable Psychiatry," to the patient and the physician. This duality of purpose diminishes rather than enhances the value of the material to the patient because it has caused to be included highly technical vocabulary and comments which are of interest to the physician alone. The general orientation of the book is largely psychoanalytic. The case reports are interestingly and convincingly told, and represent a present trend in vivid presentation of material that formerly and in some quarters is still considered to be decidedly not therapeutically advisable or advantageous. The physician who is not a specialist has much to gain from the many clinical comments about human relationships with which Dr. Hinsie amplifies his case histories. The book certainly will serve to stimulate further interest in both the layman and physician in psychiatric treatment.

**Psychiatry: A Short Treatise.** By William A. O'Connor, L.M.S.S.A., D.P.M., Medical Superintendent, Ashwood House, Kingswinford, Staffs. Cloth. Price, $9. Pp. 380. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1948.

In his introduction to this volume the author states his intentions of writing a treatise on psychiatry which, though brief, would adopt an integrative and comprehensive approach to the subject. Unfortunately, those who have longed for just such a text will be somewhat disappointed by the chapters that follow. For here, implicitly and explicitly, are the old dualisms of "mind" and "body," the familiar misleading descriptions of "mental symptoms," the same stereotyped discussions of "interview technics" and the tired, sterile kraepelinian and kretschmerian classifications of the neuroses and psychoses. Similarly, the sections on treatment, though they take occasional cognizance of dynamic concepts of abnormal behavior, rarely succeed in presenting an adequate exposition of either the science or the art of modern psychiatric therapy. This inconsistency of formulation is particularly evident in the chapter on "Psychosomatic Disturbances in the Child"; here, an unwarranted emphasis on heredity and typology vitiates otherwise meaningful and sometimes penetrating discussions of the psychiatric and medical problems of childhood.

The volume is equipped with a glossary of rather unusual definitions (sample: "The Ego: that selective constituent of the Psyche which differentiates between stimulus reception and impulse discharge") and an overelaborate index; however, there is no reference bibliography. It must, in all fairness, be stated that in view of the difficulty inherent in writing a compendium in so complex a field, Dr. O'Connor has made a commendable first attempt. Nevertheless, the first edition of his book does not as yet fulfil the current need for an authoritative text on modern clinical psychiatry.

**Calcium and Phosphorus in Foods and Nutrition.** By Henry C. Sherman. Cloth. Price, $2.75. Pp. 176, with 7 illustrations. Columbia University Press, 2960 Broadway, New York 27, 1947.

Dr. Sherman, a recognized authority in the chemistry of nutrition, presents a concise and readable account of the roles which calcium and phosphorus play in human nutrition. The quantitative distribution of calcium and phosphorus in the body and in foods is given, along with the nutritional functions of these elements.

Keeping technical terms at a minimum, Dr. Sherman explains how passable health may be obtained with a daily intake of a minimal-adequate quantity of calcium in an otherwise adequate diet, while an increased calcium intake results in higher levels of health and efficiency and better prospects for longevity. Also included are the results of direct human experimentation as well as a great number of recent experiments on animals. The bibliography, consisting of more than 550 separate references, will enable one to pursue in detail any particular phase of interest.

This book should prove invaluable to teachers and workers in the field of nutrition.

**An Introduction to the History of Dentistry. Vol. I: With Medical and Dental Chronology and Bibliographic Data. Vol. II: An Introduction to the History of Dentistry in America.** By Bernhard Wolf Weinberger, D.D.S. Cloth. Price, $20 per set. Pp. 514, with 177 illustrations; 408, with 136 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1948.

This history, presented in two volumes, records the origin and evolution of dentistry from its early beginning down through the eighteenth century. Its author spent over forty years in compiling his data, much of which he obtained from libraries, museums and antequarian societies in this and other countries. Readers will be impressed with the painstaking manner in which he has documented his material and with the fact that his careful research has uncovered new evidence on a few controversial subjects that will help correct some of the inaccuracies previously published. Throughout, the author has endeavored "to act as an interpreter or expositor of the best that has been thought and said upon the subject" rather than to set himself up as an authority. Despite this modest disclaimer, most readers will conclude that Dr. Weinberger has established himself as an able historian.

Volume I, entitled "An Introduction to the History of Dentistry," deals with ancient and medieval dentistry and is divided into three parts. Part one, consisting of fifteen chapters, describes the art and practice of dentistry in ancient Egypt, Assyria, Phoenicia, Greece and Rome. The five chapters in part two deal with dentistry during the medieval and Renaissance period, and the three chapters in part three discuss the growth of dental literature, the advent of scientific dentistry and the practice of dentistry during the eighteenth century.

Volume II, entitled "An Introduction to the History of Dentistry in America," consists of seventeen chapters. It reviews American dentistry from the early colonial period to about 1825. It contains a fund of interesting biographic data, some previously unreported, on early American dental pioneers such as Baker, Woofendale, Revere, Gordette and the Greenwoods. One complete chapter is devoted to the dental problems of George Washington.

This book is a distinct contribution to history. It is well written and profusely illustrated. The text and paper are pleasing. The casual reader may find the contents too detailed, but the student and historian will value and enjoy it.

**Treatment by Manipulation in General and Consulting Practice.** By A. G. Timbrell Fisher, M.C., M.B., Ch.B. Fifth edition of "Manipulative Surgery." Cloth. Price, $5. Pp. 275, with 126 illustrations. Paul B. Hoeber, Inc., Medical Book Department of Harper & Brothers, 49 E. 33d St., New York 16, 1948.

The restoration of joint function by manipulation, in carefully selected cases, is outlined in detail. The indications and contraindications are stressed and manipulations based on sound anatomic and physiologic grounds are outlined. The author reviews the history of manipulative therapy and points out the general neglect of its principles by the medical profession. At the same time he castigates the cults which are based on such procedures to the exclusion of modern scientific knowledge. Specific manipulative therapy for each of the skeletal articulations is outlined. The dangers are emphasized and the limitations are acknowledged. It is interesting to note that the author does not advise manipulation in cases of herniation of the nucleus pulposus. He fails to outline the signs and symptoms which would differentiate the "disk syndrome" from other conditions low in the back which may benefit from manipulative therapy.

This treatise on manipulation of joints will interest orthopedic surgeons as well as others dealing with dysfunction of joints secondary to trauma or other factors.

**Take Off Your Mask.** By Ludwig Eidelberg, M.D. Cloth. Price, $3.25. Pp. 230. International Universities Press, Inc., 227 W. 13th St., New York 11, 1948.

This book presents a fairly accurate picture of preliminary interviews together with actual reproductions of the procedure and technic of psychoanalytic psychotherapy. Dr. Eidelberg is a well trained and experienced psychoanalyst. He is also a clever man. Readers may get the impression that the author stresses his cleverness and overdramatizes the situations presented. This may have been done deliberately to accentuate the reader's interest. The reader may also get the impression that considerably more movement occurs during single interviews than usually actually occurs. This may be the result of the author's desire to condense as much material as possible into this small volume. On the whole, this is an extremely interesting, well written book. It is probably the best of its kind to be released for the general public. It is recommended reading for every one interested in dynamic psychiatry.

**Psychology.** By William James. Introduction by Ralph Barton Perry, Professor of Philosophy, Harvard University, Cambridge, Mass. [Reprint.] Cloth. Price, $1.25. Pp. 478, with 66 illustrations. Published by arangement with Henry Holt and Company by the World Publishing Company, 2231 W. 110th St., Cleveland 2, 1948.

Any student of psychology who has not read the contributions of William James should certainly do so. Many of his observations are original and extremely enlightening. Students should at the same time be warned against concluding that James has said all there is to be said about human behavior. The writings of James have enjoyed great and lasting popularity. The present volume represents an abridgement of the author's larger work, entitled "Principles of Psychology," and as such fulfils its purpose extremely well.

# Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

## TREATMENT OF POLIOMYELITIS

*To the Editor:*—Please outline the best available treatment for poliomyelitis. Is penicillin or azosulfamide ("neoprontosil") intraspinally of any value? Urban H. Zee, M.D., Lamesa, Tex.

Answer.—The virus of poliomyelitis has never been demonstrated in the spinal fluid so that no intraspinal medication has been proved of any value, or is likely to be. Neither penicillin nor azosulfamide has any effect on the poliomyelitis virus. Many laboratories are attempting to find some antibiotic or chemical that will protect animals against infection with this virus, but none has yet been proved of any value either in the prevention or the treatment of poliomyelitis infections.

The best present day treatment consists of as complete rest as possible as long as there is fever, together with such supportive measures as 10 per cent dextrose solution intravenously and the relief of pain by means of hot packs and acetylsalicylic acid. Sedatives, enough to produce artificial sleep, are contraindicated because of the danger of breathing difficulties, requiring conscious effort on the part of the patient. After the fever has gone physical therapy is instituted to recover the full range of motion in all the joints, and then a process of reeducation is begun to teach the patients again to use their muscles properly. Later, exercising for increasing strength is undertaken and then functional exercising, followed by social rehabilitation.

## MERCURY IN SPERMATOGENESIS

*To the Editor:*—Does the inhalation of "ceresan" (Dupont), containing ethyl mercuric phosphate, with exposure four months of the year, have any effect on spermatogenesis? M.D., Pennsylvania.

Answer.—A degree of similarity exists in the action of lead, arsenic and mercury. Lead is well known to exercise a blastophthoric action and is characterized as a "race" poison. Arsenic has been suspected, but as to mercury there is little evidence of a specific blastophthoric action or any other action involving spermatogenesis. In well established intoxications from any metal, including mercury, with many manifestations, it would be reasonable to accept impaired spermatogenesis as one manifestation. However, any peculiar action of mercury limited to spermatogenesis and in the absence of other characteristic features may be doubted. It is known that in mercury poisoning acidosis may be a prominent feature. It has been assumed that in such circumstances the motility of the spermatozoa may be affected. Of greater importance is the fact that in mercury poisoning psychic manifestations are prominent. These disturbances include restlessness, irritability, fear, shyness, lack of concentration, lack of confidence and general depression. This being true, any disturbance in genital function probably may better be attributed to psychic impairments rather than to direct action on specific genital organs.

## ANTIHISTAMINIC DRUGS

*To the Editor:*—Please discuss the antihistaminic drugs and their side effects. M.D., Tennessee.

Answer.—A number of preparations having the ability to counteract the effects of histamine are available. The first one available on the American market was diphenhydramine hydrochloride N. N. R. ("benadryl hydrochloride," Parke, Davis & Company), closely followed by tripelennamine hydrochloride N. N. R. ("pyribenzamine hydrochloride," Ciba Pharmaceutical Company, Inc.). Since both of these preparations frequently produced undesirable side actions, principally drowsiness, a large number of related compounds have been synthesized and studied. Among the preparations said to have fewer untoward effects are "antistin" (2-[N-phenyl-N-benzylaminoethyl] imidazoline) (Ciba), "chlorothen" (N,N-dimethyl-N′-[2-pyridyl]-N′-[5-chloro-2-thenyl]- ethylenediamine hydrochloride) and "bromothen" (N,N-dimethyl-N′-[2-pyridyl] -N′-[5-bromo-2-thenyl]-ethylenediamine hydrochloride) (American Cyanamid), "decapryn succinate" (dimethylaminoethoxy-methylbenzyl-pyridine succinate) (Wm. S. Merrell Company), "diatrin" (N,N-dimethyl-N′-phenyl-N′-[2-thienylmethyl]-ethylenediamine monohydrochloride) (William R. Warner & Co., Inc.), "histadyl" (thenylpyramine hydrochloride) (Eli Lilly & Company), "neoantergan" (N-p-methoxybenzyl-N-dimethylaminoethyl-α-aminopyridine) (Merck & Co.), "neohetramine" (2-[N-dimethylaminoethyl-N-*p-methoxy-benzyl* aminopyrimidine monohydrochloride) (Wyeth, Incorporated), "thephorin" (2-methyl-9-phenyl-2,3,4,9 tetrahydroindeno [2.1-c] pyridine) (Hoffmann-LaRoche, Inc.), "thenyllene" (methapyrilene hydrochloride) (Abbott Laboratories) and "trimeton" (prophenpyridamine) (Schering Corporation). Usually, however, therapeutic efficacy decreases as the side actions are diminished.

According to Feinberg (J. A. M. A. **132**:702, 1946) tripelennamine hydrochloride appears to have the greatest potency with the least undesirable effects. Comparisons of the newer agents have not been published, and it is not possible to state with certainty which compound has the greatest therapeutic index.

Although a number of toxic reactions have been reported following the use of antihistaminic agents (drug fever, nausea, dizziness, gastrointestinal disturbances), these are infrequent and probably represent an individual idiosyncrasy on the part of the patient. Most consistent reactions noted are drowsiness and excessive perspiration. It is advisable to use the lowest dose which will control symptoms, since these reactions appear to be a function of the dose administered.

## SULFONAMIDE AGRANULOCYTOSIS

*To the Editor:*—An article by C. A. Janeway in the March 8, 1941 issue of The Journal, page 941, states that para-aminobenzoic acid neutralizes the inhibitory effect of sulfonamide drugs in blood cultures. Could this be used to treat agranulocytosis caused by excessive doses of sulfonamide drugs? O. B. McCoy, M.D., Harrison, Ark.

Answer.—There are numerous reports on the effects of para-aminobenzoic acid in relation to the bacteriostatic action of sulfonamide drugs. However, this drug is not indicated in the treatment of agranulocytosis. In fact such a condition may be caused by the use of para-aminobenzoic acid. Menten and Graff (*Am. J. M. Sc.* **211**:672-679, June 1946) reported on the treatment of 23 patients who had granulocytopenia associated with the use of sulfonamide drugs. They administered folic acid and pyridoxine hydrochloride. Minot and Castle (Year Book of General Medicine for 1947, Chicago, Year Book Publishers, 1947, p. 436), commenting editorially on the abstract of this report, stated: "The difficulty of determining the effectiveness of therapeutic measures in sulfonamide neutropenias is manifest if one appreciates that there is convincing evidence that if (1) the offending drug is stopped, (2) no specific treatment is given and (3) the patient survives, a recrudescence of granulocytes usually occurs."

## TETRAETHYLAMMONIUM CHLORIDE

*To the Editor:*—An article in the *Cleveland Clinic Quarterly,* **15**:90-91, 1948, describes beneficial effects of early treatment of multiple sclerosis with tetraethylammonium chloride. This drug is advertised as being effective in blocking off autonomic impulses from autonomic ganglia in peripheral vascular disease. What is the efficacy of this drug in the treatment of multiple sclerosis? L. A. Cibelli, M.D., Roanoke, Va.

Answer.—Use of tetraethylammonium chloride in multiple sclerosis is based on the theory that the disease is caused by local vascular obstruction due either to spasm of the arterioles or to actual thrombosis. Agents such as the nitrites, papaverine, histamine and aminophylline have been used to combat vasoconstriction. "Dicumarol" has been used to prevent thrombosis. Although temporary beneficial effects have been noted with all of these agents none has been studied for sufficiently long periods for final evaluation. An excellent review of the diagnosis and treatment of multiple sclerosis was published in The Journal, Nov. 1, 1947, page 569, and the various theoretic considerations underlying the proposed treatments were outlined.

Evaluation of therapeutic agents in this disease is extremely difficult and patients must be followed for long periods of time before conclusions regarding the efficacy of any remedy can be drawn. Tetraethylammonium chloride has not been used in a sufficiently large number of cases under controlled periods nor have patients been observed for sufficiently long periods of time to warrant any valid conclusions.

Tetraethylammonium chloride is potentially toxic, and unpleasant. Dangerous side actions are frequently noted. Postural hypotension and effects on the gastrointestinal tract are particularly disturbing.

## PSYCHONEUROTIC VOMITING

*To the Editor:*—A 33 year old ribbon factory worker and father of three children has complained of "morning sickness" for eight years. He first began to be bothered while his wife was pregnant with their first child. She was not particularly bothered by morning nausea or vomiting. Mornings when he arises for work he is invariably seized with a sudden and passing wave of nausea and vomits a small amount of clear white to yellow bitter material. This occurs after he has been up for ten to fifteen minutes. On some occasions he has been able to eat before he vomited and he then brought up food just eaten. If he sleeps beyond 9 or 10 a. m. this difficulty does not occur. In the Navy, where he served during 1944-1945, he was studied without success in finding apparent physical or emotional cause for his complaint. All treatment has been unavailing. His weight has increased 10 pounds (4.5 Kg.) since onset of his difficulty in 1940. He has no nausea or vomiting at other times. In all other respects he is robust, healthy and well adjusted. Please suggest diagnosis and treatment.

Jesse Schulman, M.D., Belvidere, N. J.

ANSWER.—The history and absence of physical findings over a period of eight years suggest that the causation of this patient's illness is psychologic. A monosymptomatic complaint in psychoneurotic reactions of this duration is, however, rare. Recurrent early morning vomiting of an unchanging quality for a number of years without loss of weight, pain or anorexia is not indicative of a progressive lesion. Congenital or developmental defects such as diverticulum of the esophagus, diaphragmatic hernia, hypertrophy of the ligament of Treitz, compression of the duodenum by the superior mesenteric vessels or other gastrointestinal pathologic condition which causes reflex vomiting have apparently been excluded.

Medical practitioners have long recognized that the expectant father as well as his wife may suffer with morning sickness. Our information about the male's physiologic and psychologic responses to the information that he is to become a father is circulated chiefly at the anecdotal level; medical documentation, except in a few psychiatric texts and journals, is meager.

The psychologic difficulties of patients who have recurrent morning vomiting are not always on a conscious level and may be difficult to elicit by the ordinary methods of medical history taking. It is not essential that the wife be troubled with nausea and vomiting associated with early pregnancy. Male patients who present this particular complaint may have strong needs for dependency and are often submissive, propitiative, timid and unable to express appropriate degrees of aggressiveness or hostility except through their symptoms. The essential psychologic mechanisms which serve to disguise their dependent needs are identification and imitation.

The corroborative evidence required for concluding that a patient falls into this category of psychoneurosis must be derived from the evaluation of his attitudes toward himself, his wife, childen, parents, friends, co-workers and supervisors. The symptoms which usually accompany the presenting complaint are: feeling of tension, tremulousness, easy irritability and mild mood changes of a depressive quality. Treatment must be directed toward the patient's total life situation. Direct attempts to alleviate the presenting complaint are usually not successful unless a combination of experiences and events alters the patient's attitudes toward the precipitating factor, namely, the wife's pregnancy. The fact that the difficulty in this patient has persisted for eight years indicates the severity of the patient's psychologic problems.

## PARKINSONISM

*To the Editor:*—Is there a new treatment for parkinsonism? My father, aged 75, has suffered for a year with parkinsonism, probably based on cerebral arteriosclerosis. He had bronchial asthma for many years with frequent bronchiopneumonia, emphysema, bronchiectasia and from time to time slight cardiac decompensation. Blood pressure is 90 systolic and 45 diastolic. For the parkinsonism he receives atropinester[?], tincture stramonium and scopolamine hydrobromide (alternately adding 20 drops daily); at noon ½ tablet of "novydrine" (brand of amphetamine sulfate) and a sedative are administered. Improvement was unsatisfactory and the illness is progressive. Please give an exact schedule for these remedies and advise other treatment.

George Stein, M.D., Palestine.

ANSWER.—New treatment of value for parkinsonism is lacking. The remedies which have been used in this case, or other closely related drugs, are still the best treatment available. Nothing will prevent the natural progress of the disease. Usually the most effective remedy is scopolamine hydrobromide. Treatment is best started with 1/150 grain (0.4 mg.) three times a day, gradually increasing the dose and the frequency of administration until as much as 1/100 grain (0.6 mg.) five times a day is being taken. Some patients will not tolerate this much, and the dose has to be reduced accordingly. It should be borne in mind that a few patients have an idiosyncrasy for the drug and have mental confusion, delusions and hallucinations as a result of its use. This is most likely to occur in elderly patients. Tincture of stramonium may be used if scopolamine is not well tolerated but generally is less effective. Stramonium therapy is usually started in doses of 10 to 15 minims (0.62 to 0.93 cc.) three times a day and the dose gradually increased to as much as 60 minims (3.7 cc.) three times a day if the patient will tolerate it. Belladonna tincture commonly gives rise to more undesirable side effects than do the other two drugs. It is given in doses of 5 to 15 minims (0.3 to 0.93 cc.) three times a day. In recent years various preparations of belladonna root in wine and of dried extract of the belladonna root have found favor and received much unwarranted publicity. These preparations vary so widely, even in the United States, and far more the world over, that it would be impossible to recommend any particular preparation or to supply details as to dosage. In general, it may be stated that these various preparations of belladonna root seem to be more effective in cases of parkinsonism resulting from chronic encephalitis than in those forms which develop as the result of a primary abiotrophy or from cerebral arteriosclerosis. Sedatives may be used in cases of parkinsonism as they would be in any conditions requiring them. The dosage, of course, depends on the drug used. No particular sedative is more useful in cases of parkinsonism than is any other. In general, bromides are undesirable in elderly persons.

## AMEBIASIS IN ANIMALS

*To the Editor:*—In a recent lecture on colitis at New York Hospital the speaker recounted hearing a paper from the London School of Tropical Medicine on the synergistic action of Endamoeba histolytica and bacterial flora existing in the intestinal tract of mice. One set of mice (the controls) received an injection of a pure culture of E. histolytica; 100 per cent became infected. Another set of mice were given sulfadiazine before the amebas were injected. Sulfadiazine, by combating the secondary organisms in the intestinal tract, was said to prevent infection by amebas from taking place. His final conclusion was that E. histolytica needs the synergistic presence of intestinal bacteria in order to gain a foothold in the intestinal wall and survive. An interesting question presents itself: Since the mouse was 100 per cent susceptible to the disease when inoculated with the organism, why not use the mouse as the means of detection? The *Tropical Diseases Bulletin,* January 1948, page 78, states: "It has been shown that strains derived from different sources vary in their infectivity for the rat and that pathogenicity does not depend on the number of amoebae injected, or on the severity of the human infections from which they were derived. It has been shown that a strain from a symptomless carrier will produce severe lesions in the rat's caecum." Has such a clinical test been described in the literature?

A. H. Karam, M.D., New York.

ANSWER.—The questioner refers to mice in the first half of his discussion and then cites an article in which rats were used. Examination of the available literature on the subject has failed to disclose studies with mice. The infectivity of rats is variable. Jones (*Trop. Dis. Bull.* **44**:313-314, 1947, injected culture material rectally or intracecally after laparotomy into 46 three month old rats and failed to produce infection, though purging, starving, modification of diet and occlusion of the anus were tried. Better results were obtained by first establishing an infection in kittens by rectal injection of culture material and then inoculating the dysenteric stools of the kittens intracecally into 3 to 4 week old rats. Cultures of E. histolytica mixed with mucin produced infection, as did the material from the kittens. Only a small proportion of the rats showed obvious clinical signs of infection, and certain rats with massive ulceration of the cecum appeared normal clinically. The infection in rats is not readily detected by direct microscopic examination or culture of the feces. Many other investigators have succeeded in infecting the white rat, including Nagahana (1934), Takemura (1934) and Tanabe (1934). Atchley (1936) infected laboratory rats with strains of E. histolytica obtained from man and from naturally infected rats, but no lesions were observed in the animals. Kitabatake (1934) obtained infections in 64.1 per cent of 160 rats given rectal injections of material containing a strain of E. histolytica pathogenic for kittens. No dysentery symptoms appeared, but the stools became soft and scar tissue was found in the bowel.

Other animals infected with E. histolytica include the dog, cat, monkey, guinea pig and domestic pig. In dogs the infection runs a course similar to that in man. In cats, the infection is usually acute; half-grown kittens are the most susceptible to infection, which is followed by a severe and usually fatal dysentery. Some strains of E. histolytica possess only a low degree of virulence for kittens. Susceptibility in kittens was found by Kessel (1928) to be 60 per cent with amebas from acute amebic dysentery, and 49 per cent with amebas from carriers. Meliney and Frye (1937) studied the pathogenicity of cultures of E. histolytica injected into the ileum of kittens. The percentage of kittens becoming infected ranged from 20 per cent with a strain isolated in Tennessee to 90 per cent with a strain isolated in the Chicago outbreak. Chang (1945) distinguishes between infectivity and pathogenicity of E. histolytica for kittens with ligated anus. He found that loss of infectivity correlated with cessation of encystment in culture and that power of infectivity could be regained by inducing encystment.

With these considerations, the use of animal inoculation as a laboratory test for the diagnosis of amebiasis does not seem to hold promise. Conventional laboratory technics for identification of E. histolytica by a competent parasitologist are satisfactory in a high percentage of patients.

## HORMONE THERAPY

*To the Editor:*—A white married woman, aged 34, *para 1, gravida 1, first* came to me in February 1947, complaining of infertility. The history and physical examination were essentially negative. The basal metabolic rate was minus 15 per cent. Routine laboratory studies did not reveal any abnormality. Examination of the husband's seminal fluid revealed a volume of 3.5 cc. and a sperm count of 70,000,000 per cubic centimeter, with over 90 per cent normal forms and over 90 per cent motility. The previous child was a product of a former marriage. Her second marriage occurred in November 1945. She was referred to a gynecologist in April 1947. His examinations, including the Rubin test, failed to reveal any abnormality. She was placed, *at his suggestion,* on "premarin" (estrogenic substances), 1.25 mg. daily for ten days. Subsequently, she missed her next three menstrual periods, which had previously been at twenty-eight day intervals, regular, painless and of moderate three to four day flow. She had normal periods on Aug. 8 and Sept. 6, 1947. The gynecologist then suggested she be given estrogenic substance ("estrusol," 20,000 units per cubic centimeter suspension), 10,000 units intramuscularly once per week for six weekly injections. The patient has not menstruated since last menstrual period Sept. 6, 1947. She was given a course of treatment with progesterone, 5 mg. every other day for five doses. She was again seen by the original gynecologist, who suggested administration of "synapoidin" (pituitary chorionic gonadotropins), 15 units per cubic centimeter, 1 cc. every other day for five days, then 5 mg. of progesterone every other day for five days. This course was completed in April 1948. In late May she made a trip to Southern California, where she was seen by another gynecologist, who reported that the Shorr differential stain revealed pronounced estrogenic deficiency. The second gynecologist began treatment with thyroid, 1 grain (0.065 Gm.) daily, to be increased to 2 grains (0.13 Gm.) daily in two weeks if objective and subjective symptoms did not appear. At present her major interest, of course, is reestablishment of menses if possible. Can you give any suggestions?

M.D., California.

Answer.—It is unfortunate that this patient, like many others, was given estrogens and other hormones without rhyme or reason. The "premarin" which was administered when the patient menstruated regularly could not have helped her to conceive. Likewise the "estrusol" could not have had any beneficial effect. The "premarin" apparently produced temporary amenorrhea, and the "estrusol" was followed by a cessation of menstruation which has lasted more than nine months. Surely these hormone products have not helped the patient to become pregnant, but on the other hand, they most likely suppressed ovulation. "Synapoidin" and progesterone, too, are rarely useful in helping women to menstruate regularly or to conceive. The only abnormality shown by this patient is a slightly lowered basal metabolic rate. Thyroid extract should be given as suggested by the second gynecologist. In cases of definite hypothyroidism, thyroid extract will more often bring about reestablishment of menstruation and permit pregnancy than all the other hormones. Thyroid therapy should be continued for at least four months. In view of the fact that the patient is now 34 years old, if thyroid therapy is not followed by a gestation after four months, roentgen therapy should be applied to the pituitary gland, but only by someone skilled in this form of treatment.

## ALUMINUM FOIL IN TREATMENT OF BURNS

*To the Editor:*—An article appeared in the *Cleveland News* August 4, 1948, entitled "First Use of Aluminum Foil Saves Life of Burned Victim." Have you any information on this treatment?

J. B. Jack, M.D., Chicago.

Answer.—For many years there has been a search for some magic application that would solve the problem of the acute burn. Recently a great deal of sound investigative work has been done which has shown the many physiologic complications that attend the acute burn. For the first time the problem in its entirety is becoming clarified. It is obvious that the drug or material applied to the surface of the burn is probably the least important detail in the complex task of managing a burned patient. Whatever the topical agent is, it must not adhere to the wound, as does coarse mesh gauze; must not seal in infection, but permit easy removal in case of pus formation underneath; it should not be toxic, nor cause further destruction of epithelial remnants, and it should not produce pain. If aluminum foil fulfils these needs and is simply considered as one small step in the treatment of the burned patient, it would probably be as satisfactory as some of the other agents that meet reasonably well these same requirements which have been in use for some years.

## "DICUMAROL" IN CORONARY THROMBOSIS

*To the Editor:*—In using "dicumarol" in coronary thrombosis with infarction, several investigators have reported serious bleeding even though prothrombin levels have been within the prescribed limits. At other times bleeding did not occur when the prothrombin dropped to low levels. Do other factors beside the prothrombin level determine whether bleeding will occur? Is it advisable to give rutin with the "dicumarol" in order to overcome increased capillary permeability, which may be a causative factor in those patients with serious bleeding?

*Israel Pine, M.D., Belle Harbor, N. Y.*

Answer.—The goal of "dicumarol" therapy for the prevention or treatment of phlebothrombotic complications is reduction of circulating prothrombin to a level where intravascular clotting is prevented or stopped, yet not to the point where hemorrhage is likely to ensue. Experience indicates that when prothrombic activity is above 20 per cent of normal, hemorrhage is rarely, if ever, due to deficiency of prothrombin, its activators or fibrinogen. This corresponds to a prothrombin time below 30 to 40 seconds obtained with a potent thromboplastin preparation which for normal plasma will give a prothrombin time of 12 to 14 seconds.

Prothrombin activity is only one factor which operates in the over-all hemostatic mechanism. Other factors which must be considered in explaining a hemorrhage are the state of the vascular tree and the quantity and quality of blood platelets. It is conceivable that reducing plasma prothrombin activity to levels which ordinarily would not induce hemorrhage in persons with otherwise normal hemostatic function may result in hemorrhage when other hemostatic mechanisms are simultaneously disturbed. Accordingly, it is desirable to make sure that patients receiving "dicumarol" have a hemostatic mechanism normal in all other respects. The value of rutin in the maintenance or restoration of normal capillary function is still debatable. Prevention or therapy of any hemorrhagic incident must be based on elucidation of the underlying defect in hemostasis.

## HEMIHYPERHIDROSIS

*To the Editor:*—Please discuss causes, significance and relationship of unilateral sweating of the right side of face, moderately profuse, otherwise unexplained, occurring in a white man, aged 59, who had coronary occlusion in 1945. Since then he has had occasional precordial disturbance pain or tightness, dyspnea on exertion, blood pressure of 135 to 160 systolic and 70 to 80 diastolic, pulse rate of 64, temperature of 98.6 F., and a constant weight of 150 to 152 pounds (68 to 68.9 Kg.). Medication has been symptomatic—phenobarbital ¼ grain (15 mg.) three times a day; "theacitin" (theophylline sodium acetate), occasionally mannitol hexanitrate and low salt diet.

M.D., Indiana.

Answer.—Hemihyperhidrosis of the face of the type described is encountered occasionally with organic lesions involving the autonomic innervation to this area. Sometimes it is the peripheral mechanism that is involved, as in the case of the auriculotemporal syndrome, but more often the damage lies in the central autonomic centers of the brain stem, usually small focal lesions in the lateral portion of the medulla oblongata, the tegmentum of the pons or the hypothalamus. The nature of the pathologic changes varies. Congenital developmental anomalies, the gliosis of syringomyelia, tumors and small granulomas and vascular lesions are among the commonest causes. It would seem probable that in this case a minute infarct from thrombotic occlusion of a sclerotic artery in the brain stem is responsible for the condition. If the symptom is very troublesome one might carry out a procaine block of the cervical sympathetic segment in order to determine whether cervical sympathetic paralysis is effective in abolishing the sweating. If so, a more complete and permanent block or section might be considered.

## AMPHETAMINE SULFATE PREPARATIONS

*To the Editor:*—What ill effects are reported from use of d-amphetamine sulfate ("dexedrine") or racemic amphetamine sulfate ("benzedrine") in treating obesity, narcolepsy and sea sickness? What is the maximum dose?

M.D., Alabama.

Answer.—"Dexedrine" and "benzedrine sulfate" have the same actions and toxic effects. In overdosage, a rise of blood pressure, nervousness, tremors, sweating, palpitation and increased respiration may be noted. The dosage required to produce these effects varies with the individual and with his physiologic state. It is unlikely that any of the three conditions mentioned would modify significantly the toxic actions of this drug. Although toxic reactions have been noted with doses as low as 5 mg., the usual maximum dose is stated to be 15 mg. Except in severe narcolepsy it is seldom necessary to administer more than 2.5 to 5.0 mg. as a single dose and the dose should not be repeated oftener than every four hours

## POSTPHLEBITIC SEQUELAE

ALTON OCHSNER, M.D.
and
MICHAEL DeBAKEY, M.D.
New Orleans

Within the past decade many investigations have been made and much has been written concerning venous thrombosis, but relatively little attention has been paid to the sequelae of venous clotting. Without question the best treatment of the complications and sequelae of thrombophlebitis and phlebothrombosis is prophylaxis, i. e., the adequate and prompt therapy of the originating venous lesion. Unfortunately, however, some patients are not seen at the time of their original venous lesion and there are many in whom appropriate therapy is not instituted promptly enough. From our clinical and experimental investigations, we are convinced that it is necessary to differentiate between two types of venous thrombosis, which differ from each other as much as night from day.[1] Although both have in common a clot within the vein, they are dissimilar from etiologic, pathologic, clinical, prognostic and therapeutic points of view, and, unless the clinician who is treating a patient with venous thrombosis differentiates between the two types, ineffectual results are likely. Although it is not the purpose of this presentation to discuss venous thrombosis per se, in order to understand the sequelae of the two types, thrombophlebitis and phlebothrombosis should be defined. Thrombophlebitis has been known for many years. In fact, it was recognized by the ancients and was designated as phlegmasia alba dolens. As the name implies, there is an inflammation of the vein wall. This results either from bacterial invasion of the vein wall or from toxins carried to the vein through the perivenous lymphatics. The inflammatory changes in the wall of the vein produce a white thrombus which is firmly attached to the vein. Because of the firm attachment of the thrombus, unless there is suppuration which results in the liquefaction of the clot, there is little or no danger of embolism in true phlegmasia alba dolens. The symptoms, however, are pronounced. The patient complains of severe pain. There is swelling of the extremity, and there is fever. Although there is little danger as regards life, persistent sequelae develop unless adequate appropriate therapy is instituted early. On the other hand, phlebothrombosis has been recognized only relatively recently, and there has been much confusion about its differentiation from thrombophlebitis. The clot in phlebothrombosis is a nonadherent coagulum and is similar to that which forms in a test tube when blood is allowed to clot. It occurs not because of changes in the venous endothelium, but because of increased coagulability of the blood and the precipitating factor of circulatory stasis. The predisposing factor, increased blood coagulability, is due to changes in the blood constituents resulting from tissue injury. Because of the precipitating factor, circulatory stasis, phlebothrombosis occurs almost without exception in the veins of the lower extremities, where stasis is greatest. The patient with phlebothrombosis has few or no clinical manifestations. He may complain of a sense of impending disaster. There is usually tachycardia, with no commensurate rise in the temperature. Almost invariably, there is an increased erythrocytic sedimentation rate. Because of the absence of symptoms, the condition is likely not to be diagnosed unless the clinician is cognizant of its possible occurrence and examines for confirmatory signs. These signs are vein tenderness, particularly the veins of the calf muscles and on the plantar aspect of the foot, and pain in the calf or popliteal space when the foot is forcefully dorsiflexed (Homans' sign). In contrast to the absent or minimal clinical manifestations, the dangers in phlebothrombosis are considerable; in fact, death may occur. Because of this, there is great urgency for radical therapy in order to prevent the detachment of the clot which is not fixed, but which can be readily detached with the production of small or massive pulmonary emboli. As mentioned previously, the prompt recognition and the institution of adequate therapy early in the course of the disease process are of importance in both types of venous thrombosis. Not only can the process be stopped and resolution obtained in a relatively short period of time, but the undesirable sequelae which may produce death or cause chronic invalidism can be prevented.

### TREATMENT

*Embolism.*—Although the prophylactic therapy of embolism in phlebothrombosis is the ideal method of treatment and consists either of ligation of the vein proximal to the thrombus or thrombectomy and ligation before the clot has become detached, many times phlebothrombosis is not recognized until after embolism has occurred. The active therapy of a pulmonary

embolism depends largely on the size of the embolus. In massive embolism with obliteration of considerable portions of one or both pulmonary arteries, the prognosis is extremely grave and energetic radical therapy is necessary. Gibbon[2] has shown that if the lumen of the pulmonary artery is decreased to 15 per cent or less of its original size death occurs. There is considerable evidence that the severe symptoms associated with massive pulmonary embolism are only in part due to the plugging of the lumens of the pulmonary arteries, but also due to spasm of the uninvolved pulmonary vessels. Because of this possibility, measures to relieve spasm are of importance. As emphasized by Jesser and deTakats,[3] the intravenous administration of papaverine and atropine, because of their antispasmodic effects, is beneficial. Likewise, procaine hydrochloride anesthetization of the cervicodorsal sympathetic ganglions is frequently life saving, because of its vasodilating effect. The administration of high concentrations of oxygen by inhalation is imperative, in order to improve respiratory and cardiac functions. The prompt administrations of anticoagulants, preferably heparin because it is much more readily controlled, is desirable in order to prevent propagation of a thrombus in the pulmonary vascular bed.

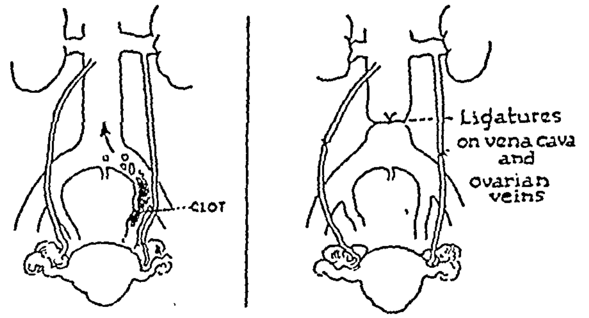

Fig. 1.—Diagrammatic representation of treatment of suppurative thrombophlebitis originating in a septic uterus. In order to prevent entrance of the septic emboli into the systemic circulation, ligation of the vena cava and the two ovarian veins is done. In this way, the transportation of the septic emboli to the lungs and the systemic circulation is prevented.

Although embolectomy, as originally suggested by Trendelenburg, was rather popular several decades ago; now it is infrequently used. The number of patients who have been saved by this heroic procedure is so small that it offers relatively little in the treatment of pulmonary embolism. Certainly one is not justified in watching the patient who has had one or more nonfatal infarctions until fatal embolism occurs, as has been suggested and practiced by continental surgeons. In such an instance, it is far better to prevent further pulmonary embolism by the thrombectomy or ligation of the vein in which the thrombus is located. As previously emphasized by us,[1h] there is no other condition except hemorrhage which takes precedence over phlebothrombosis as regards urgency of therapy, because of the possible dangerous sequelae.

Pulmonary Embolism: In most cases of pulmonary embolism, a fatality does not occur with the first embolism; in fact, according to Barker, Nygaard, Walters and Priestley[4] only 24 per cent of pulmonary embolisms are fatal within the first attack. According to Zink,[5] 70 per cent of patients with fatal pulmonary emboli have had an antecedent infarction. As emphasized by Barker and his co-workers,[4] the occurrence of multiple episodes of pulmonary embolism terminates fatally in about 60 per cent of patients. They also found that in all cases of fatal embolism the final attack was preceded by one or more nonfatal attacks in 36 per cent. In nonfatal pulmonary infarctions, the clot is smaller, producing obstruction in the smaller branches of the pulmonary artery. This results in infarction of the lung, which is of importance not only because of its associated pneumonitis but also because of the warning that the patient has a focus from which emboli can originate and can end in fatal embolism.

*Septic Infarction and Septicemia.*—Whereas embolism is usually the result of phlebothrombosis and is rarely seen in thrombophlebitis, it can occur exceptionally as a sequel to the latter condition. Most emboli complicating thrombophlebitis are the result of suppuration. The liquefying action on the clot of suppurative process loosens the otherwise firmly attached thrombus and permits its detachment. This sequel is particularly dangerous not only because of the development of embolism, but also because the embolus is infected resulting in septic infarction of the lung and possibly septicemia. We have had opportunity to observe a rather large number of such cases in the Charity Hospital in New Orleans, most of them being cases of suppurative thrombophlebitis of the pelvic veins resulting from criminal abortion. Neuhof and Seley[6] reported 93 cases of acute suppurative phlebitis complicated by septicemia and emphasized the fact that in most cases there was a demonstrable suppurative or acute inflammatory process in the immediate vicinity of large venous radicles. Twenty-one per cent complicated otitic infections; 20 per cent originated in areas drained by the portal system, and 46 per cent originated in the extremities and neck. It is of interest that 6 cases (6.4 per cent) followed cut down intravenous infusion or prolonged intravenous infusion at a single site. Suppurative thrombophlebitis is a condition which is extremely serious because of its potentialities. Although if untreated the condition is usually fatal, death is not the result of massive pulmonary embolism as in phlebothrombosis, but is from sepsis. In order to prevent the systemic invasion by septic emboli, ligation of the veins proximal to the suppurative thrombophlebitic process or excision of the involved segment of vein is imperative. As demonstrated by Collins,[7] Professor of Gynecology at Tulane, the patient suffering from suppurative thrombophlebitis of the pelvic veins complicating septic abortion is best treated by ligation of the inferior vena above its bifurcation and ligation of both ovarian veins (fig. 1). Although previously the mortality rate from such a lesion was extremely high, it is now low. Zaufal,[8] in 1880, was apparently the first to treat suppurative thrombophlebitis by vein ligation when he ligated the internal jugular vein in a patient with an infection of the internal ear, resulting in a sinus thrombosis. As early as 1901, Viereck[9] showed statistically the value of vein ligation in such cases. In a collected series of 108 cases, 89 patients recovered. Collins[10] and his associates ligated the inferior vena cava and ovarian veins in 28 patients for suppurative thrombophlebitis with suppurative thrombophlebitis of the pelvic vein, with only 5 fatalities. On the surgical service we have performed five inferior vena caval ligations of suppurative pelvic vein thrombophlebitis originating in the lower extremities, with no fatalities. By the prompt proximal ligation in suppurative thrombophlebitis not only recurrent septic infarction but also sepsis will be prevented. After vein ligation the administration of bacteriostatic agents will control the pneumonitis resulting from septic infarction. However, occasionally, an abscess of the lung will develop in the infarcted area, which may require drainage.

*Coagulation Thrombus.*—An even rarer type of embolism occurring in thrombophlebitis is the coagulation or red thrombus, which occurs in the vein proximal to the thrombophlebitic segment and which results from inadequate therapy during the acute stage of thrombophlebitis. If a patient with acute thrombophlebitis is kept quietly in bed, there is a possibility of a coagulation thrombus developing in the segment of vein between the area of thrombophlebitis and the next venous tributary. Although this is a coagulation thrombus, not attached to the vein wall and not likely to become detached, it is of short length and, even should it become detached, is likely to produce minimal manifestations. This coagulation thrombus can be prevented, however, by mobilization of the patient during the treatment of the acute thrombophlebitis. In addition to the pneumonitis associated with nonfatal pulmonary infarction, another possible complication of embolism which occurs infrequently is pulmonary arterial fibrosis, which has been emphasized by Belt.[11]

*Edema.*—Although, as emphasized previously, thrombophlebitis is relatively rarely complicated by embolism, in most cases persistent, annoying, uncomfortable and disabling sequelae develop unless adequate therapy is instituted during the acute phase of the venous lesion. The persistent postphlebitic sequelae consists of edema, ulceration and recurrent streptococcic infection. Whereas in some cases, all three of these processes occur concomitantly, because all may be due to the same disturbed physiologic mechanism, the cause of each is not necessarily the same.

Without question, the most frequently encountered postphlebitic sequel is edema. In fact, there are few cases of phlegmasia alba dolens which if not treated promptly and adequately by vasodilation during the acute phase of the process will not have persistent edema. We have previously shown, both experimentally and clinically, that in the acute phase of thrombophlebitis, although the lesion is within the vein, the symptoms, namely, pain, swelling, and persistence of fever, are the result of associated reflex arteriolar spasm. By early vasodilation during the acute phase of thrombophlebitis there is a prompt subsidence of all clinical manifestations and rapid resolution of the inflammatory process. Instead of the persistence of the symptoms and the development of sequelae, the patients are, with few exceptions, well within a week or ten days. Although it has been definitely proved that the edema during the acute phase of thrombophlebitis is due to vasospasm and the resulting relative anoxia of the capillary endothelium, causing the exudation into the perivascular spaces, it has been difficult to envision that vasospasm is responsible for the persistent edema occurring as a postphlebitic sequel. In fact, for many years we doubted whether the persistent postphlebitic edema could be caused by vasospasm. Approximately twelve years ago we saw a patient who six years previously had had severe thrombophlebitis complicated by persistent disabling edema. Because her physicians had told her that vasodilatation was beneficial in acute thrombophlebitis, she insisted that procaine hydrochloride anesthetization of her regional sympathetic ganglions be done even though there was no evidence of vasoconstriction. Although we anticipated little improvement, a dramatic decrease in the size of the extremity was observed after vasodilatation. Since this time we have become increasingly impressed by the importance of vasospasm as a causative factor in persistent postphlebitic edema. Although clinically there is no evidence of vasospasm, such as the coldness and whiteness of the extremity which are prominent during the acute phase of phlegmasia alba dolens, in approximately 90 per cent of cases after procaine hydrochloride anesthetization of the regional sympathetic ganglions there is increased warmth and a decrease in the size of the extremity. Because it is the most frequent cause, we believe that in every case of postphlebitic edema one should determine whether vasospasm is a factor or not. This is accomplished easily by measuring the circumference of the extremity at several levels. Using a bony line mark at the knee, such as the joint space, measurements are made at the knee, at a prominent portion of the calf and just above the ankle (fig. 2). Similarly, two such measurements are made on the thigh. After mensuration, the patient is instructed to walk at his normal gait for a distance of approximately a mile, after which the measurements are again repeated and a procaine hydrochloride block of the regional sympathetic ganglions performed (fig. 3). The patient then, as previously, walks the same distance at the same rate of speed. After the completion of this tour, measurements of the circumferences of the extremity are remade and compared with the two previous measurements. If there is a decrease in the circumference of the extremity after the sympathetic block, one is

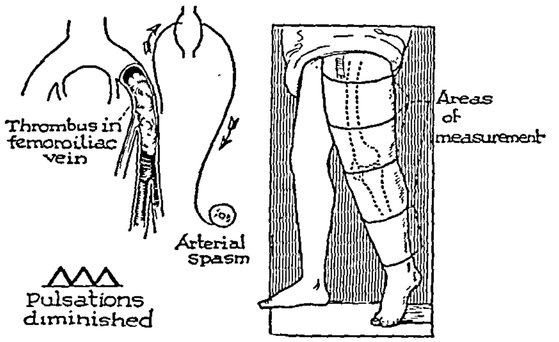

Fig. 2.—Diagrammatic representation of persistent postphlebitic edema produced by vasospasm. Because of the irritation of the venous endothelium, impulses are carried over the sympathetic nervous system, producing spasm of the accompanying arterioles. Measurements of the extremity are made at five levels: two in the thigh, two in the leg and one at the knee, using the bony landmark of the knee for determining the sites of measurement.

justified in assuming that vasospasm is a factor in producing the edema (fig. 4).

The treatment of a patient with postphlebitic edema which is due to vasospasm may be either conservative or radical. As most of the patients are housewives, who are able to arrange their day more or less arbitrarily, conservative therapy is to be preferred and unusually is radical therapy necessary. The patient should avoid those measures which produce vasoconstriction, such as smoking and exposure to cold, and should avoid becoming emotionally upset. They are instructed to use compression applied before arising in the morning either by elastic bandages ("ace" no. 8, "lastex") from toes to the knee or by elastic stockings. We prefer the bandages, because although an elastic stocking is easier to use and is slightly less objectionable to the patient as regards its appearance, it has the disadvantage of stretching and not fitting properly after a few days. Even though the elastic bandage ("ace" no. 3) similarly stretches, it is applied daily to conform to the size of the leg that particular day. The avoidance of chilling, particularly during the night, is important, and an electric blanket is valuable. The length of time required for the complete subsidence of the edema in such a case is several months to a year or longer, but the improvement is usually progressive and finally complete. In the person who is more or less incapacitated because of edema resulting from vasospasm, such as the laborer who stands at a lathe or other machine, and in whom a rapid recovery is desirable, sympathectomy is recommended. This brings about permanent and complete vasodilatation and results in a reestablishment of the normal size of the extremity more rapidly. It is possible that the increase in the blood supply to the extremity by increasing arteriolar pulsations, which, as shown by McMaster[12] and Blalock,[13] are responsible for movement of the lymph, is a factor in reducing the size of the extremity in these patients.

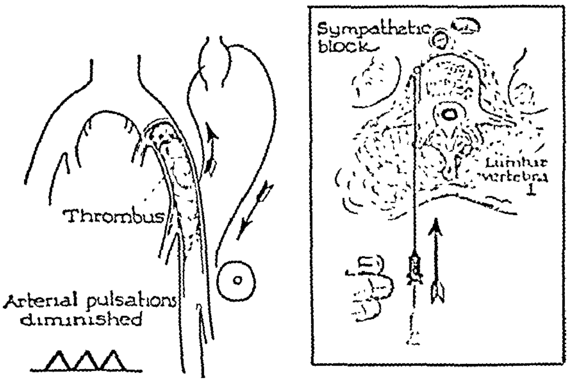

Fig. 3.—Technic of lumbar sympathetic block. With the patient in the supine position or in the lateral decubitus position, points 2 fingerbreadths lateral to the spinous processes of the first, second, third and fourth lumbar vertebrae are located and cutaneous wheals with procaine hydrochloride made at each, with a *long fine needle* (5½ inch, B.D., 20 gage). The needle is introduced through each of these points until it hits the transverse process The direction of the needle is then changed slightly, either above or below, and introduced for an additional 2 fingerbreadths. The spinous process serves as a landmark, because whereas there may be considerable difference in the thickness of the erector spinae mass and the subcutaneous fat of a large obese muscular man and a little thin woman, there is not much difference in the thicknesses of the bodies of their vertebrae. Through each one of the four ports, 5 cc. of 1 per cent procaine hydrochloride is injected.

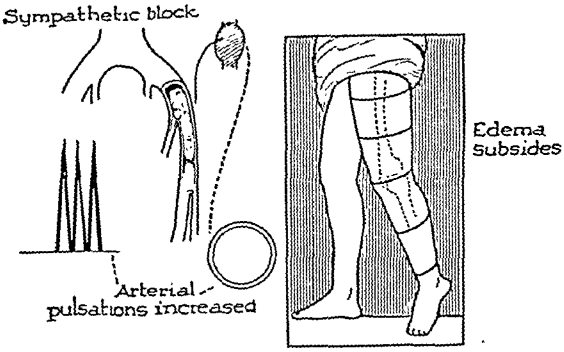

Fig. [illegible] representation showing decrease in the size of the [illegible]odilatation produced by lumbar sympathetic block. [illegible] one can assume that the persistent edema is due to persistent vasospasm.

Because of the beneficial effect of skeletal muscle contraction in the movement of blood and lymph in the extremities, patients with postphlebitic edema are instructed to walk considerably but to refrain from standing. If they are required to stand in one position for any length of time, they should contract their calf muscles by standing on their toes from time to time, in order to facilitate lymph movement.

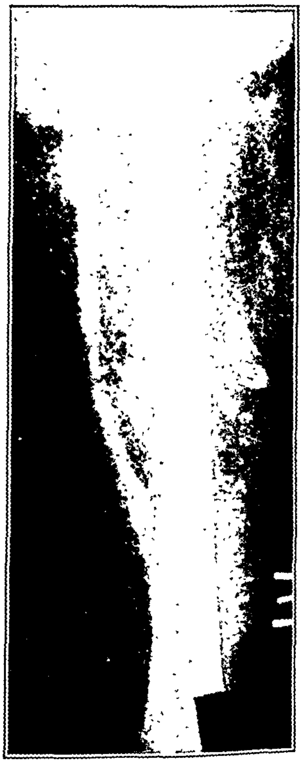

Fig. 5.—Phlebogram of a patient with persistent postphlebitic edema, but in whom vasodilatation produced by lumbar sympathetic block did not result in a decrease in the size of the extremity. Phlebogram shows the deep veins not only patent, but also dilated.

Although 90 per cent of our patients with persistent postphlebitic edema have sufficient vasospasm to cause the edema, there are a few (approximately 10 per cent) in whom the edema is not the result of vasospasm. By a process of elimination one determines whether postphlebitic edema is caused by vasospasm or not. In those patients not benefited by vasodilatation, the edema is due to some other factor. Edwards,[14] Homans,[15] Buxton and his co-workers[16] and Linton[17] maintained that postphlebitic edema results because of destruction of the valves in the deep veins by the thrombophlebitic process. Although these observers stated the belief that this is the most frequent cause of postphlebitic sequelae, from our own experience we are convinced that this represents a relatively small group (less than 10 per cent). The patient who is not benefited by

vasodilatation should have careful phlebographic examinations in order to determine whether the deep veins are patent or not. From our experience the persistence of edema in a patient in whom vasospasm is not the cause is the result of one of two types of lesions: one in which the deep veins are patent and function as a channel through which the blood can be carried, but in which the valves are incompetent because of their destruction by the previous inflammatory process in the vein permitting reversal of blood flow, and another in which the vein does not recanalize but is obliterated and embedded in dense perivenous scar. Phlebograms will differentiate between the two types of lesions. Although phlebographic examination will not determine the presence of perivenous scar, we believe that with evidence of obliteration of the deep venous system one can assume there is associated perivenous fibrosis.

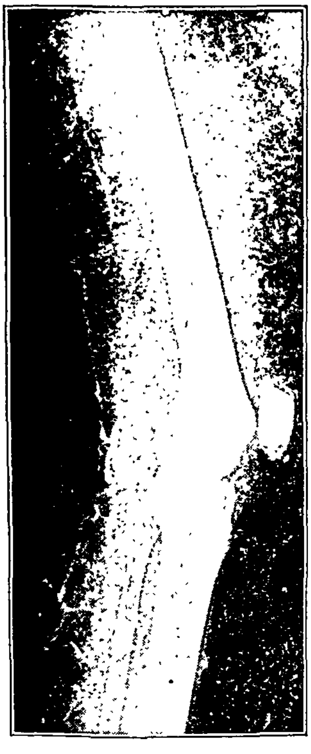

Fig. 6.—Phlebogram of a patient with persistent postphlebitic edema in whom vasodilatation secured of lumbar sympathetic block did not result in decrease in the edema. The phlebogram shows complete absence of filling of the deep veins with the development of extensive collaterals in the superficial veins.

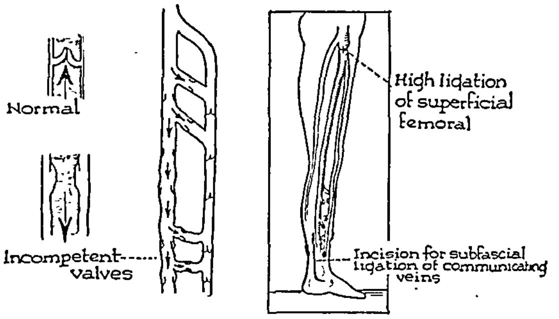
*Incompetency of Valves.* — Incompetence of the valves of the deep venous system, because of their destruction or fixation by the previous severe thrombophlebitis, results in reversal of blood flow in the deep veins with the patient in upright position. Because of this, tremendous head pressures are exerted on the valves of the communicating veins, producing their incompetence. The increased pressure in the deep venous system is then exerted in the superficial veins, producing pronounced stasis in the dependent portions of the legs, particularly in the region of the internal malleolus. Because of this there is the likelihood of other sequelae besides edema, such as dermatitis and ulceration.

It may be assumed that in a patient with persistent postphlebitic edema, who is not benefited by vasodilatation and in whom there is phlebographic evidence of deep vein patency, the valves of the deep veins are incompetent (fig. 5). The treatment in such a case consists of exposure of the deep veins in Hunter's canal and ligation of the superficial femoral vein (fig. 7).

*Ulceration.*—If there is an associated ulceration, it has been our custom to perform a preliminary sympathectomy on that side, not with the idea of overcoming vasospasm and correcting the edema, because preliminary examination has demonstrated that the vasospasm is not a factor in the production of edema, but in order to increase the vascularity of the part and to favor healing. In addition to ligation of the superficial femoral vein, we have ligated subfascially the communicating veins beneath the ulcer and in this way have been able to secure rapid healing of the ulcer and ultimate good results (fig. 7). A few of these patients have subsequently had superficial varicosities, which have been treated according to their manifestations. Generally, we have done high ligation of the saphenous at the fossa ovale, with all its tributaries, and stripped the long saphenous vein.



Normal
Incompetent valves
High ligation of superficial femoral
Incision for subfascial ligation of communicating veins

Fig. 7.—Diagrammatic representation of treatment in patients with postphlebitic edema due to incompetent valves of the deep venous system. The superficial femoral vein is ligated, and in those instances in which there is an incompetence of the valves of the communicating veins, particularly in the legs, usually associated with ulcer, an incision is made beginning below the internal malleolus and extending up posteriorly and superiorly in order to permit subfascial ligation of the communicating veins. The edema in this instance is due to increased venous pressure and retrograde flow in the deep venous system.

*Perivenous Cicatrization.*—In the patient with persistent edema which is not due to vasospasm, as determined previously by vasodilatation with sympathetic block, and in whom phlebographic examination determines an absence of filling of the deep veins, one can assume that edema is due not to increased venous pressures because of incompetence of the deep vein valves, but probably to excessive perivenous cicatrization (fig. 6). The dense fibrous tissue mantle surrounding the vascular bundle predisposes to edema in two ways: by preventing dilatation of the canaliculi in the organized venous thrombus and by interfering with reestablishment of normal lymph channels and lymph flow. These patients are best treated by the "unbridling" operation suggested by Jennings.[18] Exploration of the involved vein in Hunter's canal or in the pelvis reveals a pronounced perivenous cicatrix with extensive constriction of the involved vein. With considerable difficulty this fibrous tissue mantle is dissected away and the vein and artery are free (fig. 8). Whether the

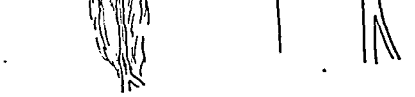


Fig. 8.—Diagrammatic representation of the treatment of patients with persistent postphlebitic edema not due to vasospasm and in whom phlebogram shows absence of filling of the deep venous system. The persistent edema in this instance is due to decided constriction of the involved vein and the extensive perivenous scar. The treatment consists of freeing the vein and removing the excessive scar throughout the entire extent of involvement.

---

[18] Jennings, J. E.: Choked Leg, Ann. Surg. 98:928, 1933.

removal of constricting influence of the perivenous scar results in sufficient dilatation of the canaliculi in the organized vessel to decrease venous obstruction or whether the removal of the perivenous fibrous tissue mass favors the development of new lymphatic channels, one is not able to say. The fact remains, however, that this procedure has been followed by decided improvement in the cases in which it has been done.

*Streptococcic Infection.*—A relatively infrequent sequel to thrombophlebitis, but one which is entirely preventable, is recurrent erysipeloid infection. Sabouraud[19] and Unna[20] were the first to call attention to the etiologic significance of streptococci in cases of progressive lymphedema associated with erysipelas-like attacks. Matas,[21] the first Hodgen lecturer, in 1911 and later in 1913 described the similarity of the clinical picture of recurrent erysipelas and that of acute attacks of recurrent lymphangiitis occurring periodically in cases of recurrent lymphedema which terminates in elephantiasis. As has been shown by Drinker and his associates,[22] the persistence of edema favors the development of streptococcic infection. They demonstrated that dogs which normally are resistant to hemolytic streptococcic infection become extremely susceptible locally in the presence of edema resulting from lymphatic obstruction. Because of this, it is imperative that in all persons in whom there is a tendency for edema to develop every measure must be taken to prevent the persistence of the edema and development of the inflammatory process. This can be obviated largely by the adequate control of the edema by use of compression bandages and the prevention of the streptococcic infection in the edematous area. The recurrent attacks of erysipeloid infection consist of chills and fever associated with burning, itching, pain and redness of the extremity. The streptococci usually gain entrance to the extremity through breaks in the skin and the infection is especially likely to be associated with fungous infections, such as epidermophytosis. Thompson[23] has emphasized the importance of sensitization to fungi in the development of these symptoms. Although the edema following uncomplicated thrombophlebitis is relatively easily controlled by rest in bed and elevation of the extremity or the use of compression bandages and exercise, the swelling of the extremity associated with and subsequent to recurrent erysipeloid infection of the edematous extremity does not subside with bed rest. This is because of the deposition of scar as the result of the infection. Although edema is a prominent part of this picture, the edematous fluid is encapsulated in small lacunas of fibrous tissue and cannot be carried away as normally occurs. In the recurrent erysipeloid infection a vicious circle is set up. The edema predisposes to infection and the infection in turn increases the edema because of the deposition of scar tissue, and ultimately true elephantiasis results.

The therapy of recurrent streptococcic infection of the lower extremity associated with edema consists primarily of prophylaxis, i. e., the control of edema and the prevention of streptococcic infections in patients with incipient edema. The incidence of this condition is much greater in the South, probably because of the higher incidence of epidermophytosis, resulting from the warmer climate and excessive perspiration of the feet. In many cases a sympathectomy is advisable in order to produce anhydrosis of the feet and thus prevent skin maceration, epidermophytosis and streptococcic infection. It must be emphasized that the sympathectomy in such cases is done because of its dehydrating effect and not to produce vasodilatation. Matas suggested that because of the streptococcic infection an attempt should be made to immunize the patients by repeated injections of polyvalent streptococcic antiserum over a long period of time. We used this method of therapy for a number of years, but, as previously reported,[24] discontinued it because the results were not good enough to justify its continuation. On the suggestion of Dr. Hugh Trout,[25] for a number of years we have used 3 to 4 Gm. of sulfadiazine daily for a week each month over a period of a year. Although this therapy has been satisfactory in controlling the recurrence in practically all cases, it is probably not without danger because of the possible hazard of the development of sensitivity to sulfonamide drugs. In those persons who experience toxic manifestations from sulfonamide drugs, we use penicillin. The treatment of the acute attack consists of immediate rest in bed and the prompt institution of antibiotic therapy, preferably penicillin, in order to minimize the amount of infection and to cut as short as possible the course of the disease. Any foci of infection within the body through which micro-organisms might gain entrance or from which they might originate must be removed. We previously reported the case of a boy who had had a severe third degree burn of the right lower extremity, which caused extensive cicatrization of the popliteal space. As a result of this relatively nonviable scar, a recurring ulcer developed in the popliteal area. Typical erysipelas developed, which recurred many times. After excision of the scar and ulcer and the application of a pedicle graft from the opposite thigh to the popliteal area, the patient became completely free from symptoms in fourteen years. It is obvious in this instance that the stress on the scar tissue in the popliteal area prevented the healing of the ulcer, which, although at a point some distance from the focus of infection, served as the portal of entry for organisms responsible for the recurrent attacks of streptococcic infection. In the case in which there have been repeated attacks resulting in deposition of considerable scar with the production of elephantiasis, it may be necessary to resort to radical procedures, such as a modified Kondoleon operation, because only by such therapy can the excessive subcutaneous fibrous tissue, which is responsible for the persistence of edema, be removed.

### SUMMARY AND CONCLUSIONS

Post-thrombotic sequelae are extremely serious in that they may end fatally or, at best, produce disabling symptoms. Although of serious importance, they can be prevented; if prompt, adequate therapy is used early in the course of the venous lesion, not only will the progress of the thrombosing process be stopped but the undesirable sequelae will be prevented.

Fatalities following venous thrombosis are usually the result of embolism. Massive pulmonary embolism resulting from the detachment of a large nonadherent clot in phlebothrombosis is likely to cause sudden death. The detachment of smaller portions of a coagulation thrombus in phlebothrombosis results in pulmonary infarction and subsequent pneumonitis. They are of significance not only because of the development of the pneumonitis, but because they indicate the presence of a thrombus which can become loosened and produce fatal pulmonary embolism.

Death may be caused by emboli in suppurative thrombophlebitis. Although the clot originally in this lesion is firmly fixed to the vein wall and will not become detached, as a result of the liquefying action of the suppurative process, the clot can be softened with the production of multiple septic emboli. Death in such an instance is not from massive pulmonary embolism as in phlebothrombosis, but is from septic infarction of the lung and sepsis.

With the exception of suppurative thrombophlebitis, fatalities usually do not occur in cases of thrombophlebitis. The reason for this is that the clot in thrombophlebitis is firmly attached to the vein wall and there is little danger of its becoming detached with the production of an embolus. Thrombophlebitis, however, unless adequate therapy is instituted early during the course of the disease, is likely to be followed by disabling persistent sequelae. The principal sequelae are edema, ulceration and recurrent streptococcic infection.

Edema is by far the most frequently encountered post-thrombotic sequel. In fact, there are few cases of true phlegmasia alba dolens in which early adequate therapy is not used in which post-phlebitic edema does not develop. Edema may be due to one of three causes: (1) persistent vasospasm, (2) increased venous pressure due to incompetence of the valves of the deep veins and retrograde blood flow in them, decidedly increasing the filtration pressure (this type of edema is likely to be associated with ulceration of the dependent portion of the leg), and (3) pronounced perivenous cicatrization, producing interference with the return flow of blood through the deep venous system. In order to determine the type of lesion in postphlebitic edema, it is necessary to determine whether vasospasm is present or not. If vasospasm is present, measures to produce vasodilatation usually result in complete recovery. In the absence of vasospasm, it is imperative to make careful phlebographic studies to determine the patency of deep veins. If the deep veins are patent, there is almost invariably an incompetence of the valves of the deep veins with reversal of flow in them, usually with associated incompetence of the valves of the communicating veins, particularly in the lower leg. The treatment in such an instance consists of ligation of the deep veins, particularly the superficial femoral and the subfascial ligation of the communicating veins in the leg. This will benefit not only the edema, but also the associated ulceration in the lower portion of the leg. If phlebographic examination shows an absence of filling of the deep veins, one can assume that the edema is due to a definite perivenous cicatrix, particularly in the femoroiliac area, producing obstruction of the deep venous flow and probably interference with the reestablishment of normal lymphatic channels. These patients are best treated by "unbridling" of the constricted vessel by removal of the perivenous scar. This presumably permits the dilatation of the canaliculi in the organized segment and the possible development of new lymphatic channels in the perivenous area.

Postphlebitic ulceration is usually the result of incompetence of the valves of the deep veins and an incompetence of the valves of the communicating veins. The correction of these abnormalities results in a healing of the ulcer.

Recurrent streptococcic infection occurs as a result of persistent edema and the introduction of streptococci into the edematous area. These usually gain entrance through fissures on the feet as a result of epidermophytosis. Characteristically, the condition is a chronic recurring one with the production of an excessive amount of subcutaneous scar tissue. The treatment consists primarily of prophylaxis, i. e., the prevention of edema and the prevention of contamination with streptococci. Compression bandages are used to prevent the edema, fungous infection of the feet is controlled and anhydrosis of the feet produced in susceptible persons by the performance of a sympathectomy. Once a streptococcic infection has occurred, the administration of sulfonamide drugs, 3 to 4 Gm. daily for a week out of each month for several months, will generally control the infection.

# MECHANISM OF THE POSTGASTRECTOMY SYNDROME

DAVID ADLERSBERG, M.D.
and
ERNST HAMMERSCHLAG, M.D.
New York

Partial gastrectomy remains at present the method of choice in the surgical treatment of peptic ulcer. Studies of the past few years regarding vagotomy alone or in combination with gastroenterostomy or gastric resection do not as yet permit a final evaluation of this procedure. A recent discussion on vagotomy[1] disclosed a considerable difference of opinion with regard to the selection of cases, the technical procedure and the postoperative complications. Many more years of study will be necessary to answer these questions, so that at present vagotomy is still on trial. In contrast, partial gastrectomy has been practiced for many years in all parts of the world and considerable experience is available concerning immediate and late results. With advancement of technic, postoperative mortality has been reduced to a minimum and the final results appear to be in general satisfactory. Jejunal ulcer, exceedingly common after gastroenterostomy, represents a rare complication of gastric resection. In one of the

A., and Colp, R.: Supradiaphragmatic Vagotomy in Gastrojejunal Ulceration Following Subtotal Gastrectomy for Duodenal Ulcer, S. Clin. North America. **27**: *249* (April) 1947.

recent reviews of 615 cases of gastrectomy, followed up over a period of years, marginal ulcer was observed in only about 1 per cent of the cases.[2]

Despite absence of jejunal ulcer, a group of these patients show postprandial distress and weakness and are unable to gain weight, symptoms which may interfere seriously with their daily life. This clinical observation has been made, irrespective of the surgical method employed, in various hospitals throughout the world.[3] The extensive literature on this subject proves that gastroenterologists, as well as surgeons, have recently become increasingly interested in the unfavorable sequelae of partial gastrectomy in persons without jejunal ulcer who, according to various statistics, represent 6 to 38 per cent of all patients on whom this operation has been performed for peptic ulcer.

In a previous study, an effort was made to classify and clarify these symptoms, for which the term "postgastrectomy syndrome" was suggested.[4] Analysis of the underlying mechanisms is the purpose of this communication.

CLINICAL CHARACTERISTICS

This study included 20 patients with partial gastrectomy who were observed during the past five years at the Nutrition Clinic of the Mount Sinai Hospital in New York city. A part of this material was reported in a previous publication.[4] All patients presented nutritional problems and were decidedly underweight. During the course of observation a careful study of symptoms and underlying causes was attempted. It included clinical examination, roentgenographic studies, laboratory analyses, psychosomatic studies and determination of the response to various types of high caloric, high protein, high fat, high vitamin diet, supplemented with vitamin concentrates and liver extracts. With few exceptions the therapeutic results were unsatisfactory.

Of the 20 patients, 19 had had gastric resection for peptic ulcer and 1 for gastric syphilis. Of the 19 ulcer patients, 14 had duodenal ulcer and 5 gastric ulcer before operation. In 1 instance a subdiaphragmatic vagotomy was performed at the time of the gastric resection. As in the previous publication, patients with resection for gastric carcinoma were purposely not included, since undiagnosed recurrence of the original disease may in these patients be the cause of loss of weight and poor nutritional status. Eleven of the patients were men and 9 women. The age of the patients at the time of this study was 32 to 73 years, with an average age of 51 (table 1). The high average age of the group is explained by the long duration of symptoms before and after operation. The age at the onset of symptoms was 15 to 53 years, the average age 32, and at time of operation it was 29 to 55 years, with an average of 42. Thus, these patients were confronted with ulcer symptoms at the average age of 32, and with gastrectomy at 42, while the average age at the time of this study was 51.

Reliable information regarding weight at onset of ulcer symptoms was obtained from 15 patients and regarding weight at time of operation from 17. The body weight before the onset of symptoms was 114

to 190 pounds (51.7 to 86.2 Kg.), an average of 140.6 pounds (63.8 Kg.); the weight before operation was 70 to 162 pounds (31.8 to 73.5 Kg.), with an average of 126.1 pounds (57.2 Kg.). At the time of this study, weight ranged from 90 to 166 pounds (40.8 to 75.3 Kg.), with an average of 114.6 pounds (51.9 Kg.). Thus, the average loss of weight before operation was 14.5 pounds (6.6 Kg.) and after the operation 11.5 pounds (5.2 Kg.), totaling 26 pounds (11.8 Kg.). The nutritional status of these persons was not improved by the operation but showed additional deterioration.

## SYMPTOMS

The clinical features of the postgastrectomy syndrome have been adequately described by all authors interested in the subject. It consists of weakness, tiredness, fatigue, inability to gain weight and to work; postprandial symptoms of distress, fulness, nausea, eructation, belching, perspiration, dizziness, palpitation and various additional vasomotor symptoms, and, finally, occasional intestinal symptoms of constipation or diarrhea. All patients of the group had a good functioning stoma. Persons with a poorly functioning or nonfunctioning stoma were not included. An attempt was made to evaluate the frequency of the symptoms in our group of patients (table 1). Weakness and/or pronounced fatigue, particularly after meals, was present in 19 patients, and was the most frequent complaint; postprandial fulness and/or nausea, in 17; dizziness, mostly in conection with meals, in 17; eructation and/or belching, in 15; constipation, in 10, and diarrhea, in 5.

The general symptoms of dizziness, palpitation, profuse perspiration and weakness resulted in some instances in fainting or compelled other patients to lie down after meals in order to prevent syncope.

Despite marked underweight of all patients, evidence of vitamin deficiency was not frequent. Only 5 persons presented clinical signs of vitamin deficiency, sore mouth, reddening and hypertrophy of lingual papillae and in 2 instances cheilosis. The other patients showed only milder signs of nicotinic acid and/or riboflavin deficiency in the mucous membranes of the oral cavity and occasionally dry skin with hyperkeratosis and folliculitis, evidence of mild vitamin A deficiency.

Of additional clinical findings, only the most important should be mentioned: bronchiectasis and shrinkage of the lower lobe of the right lung in patient 8, evidence of gout in patient 12, mild thromboangiitis obliterans in patient 13 and Wassermann positive latent syphilis, including gastric syphilis, in patient 14. In patient 17 with arteriosclerotic heart disease, the relationship between postprandial hypoglycemia and angina pectoris became apparent in the course of observation, as may be seen from the following report.

K. F. was a 74 year old white man and a physician. Subtotal gastrectomy for gastric ulcer had been performed in 1925. Although the patient continued to practice medicine until nine years ago, he never felt well. Chief complaints were weakness, poor nutritional status, epigastric discomfort after meals, dizziness, perspiration and, more recently, precordial pain two to three hours after meals. Transurethral prostatectomy was performed in 1946. Weight at that time was 115 to 116 pounds (52.1 to 52.6 Kg.). In the last two years the postprandial symptoms, weakness, fatigue and the precordial distress became so pronounced that the patient was practically always confined to his home.

On physical examination, the patient was pale and emaciated, and looked chronically ill. His weight was 113 pounds (51.3 Kg.). Pulse rate was 72; blood pressure measured 100 mm. of mercury systolic and 72 diastolic. Heart sounds were normal with no murmurs. The abdomen showed a scar in the epigastrium; there were no masses palpable, and the liver and spleen were not enlarged. The urine gave no reaction for albumin and sugar. There was moderate secondary anemia: hemoglobin concentration, 68 per cent; 4,125,000 erythrocytes and 5,700 leukocytes with a normal differential count. Gastric analysis showed absence of free hydrochloric acid. Roentgenographic examination of the gastrointestinal tract revealed a small gastric stump with rapid emptying into the jejunum. There was also rapid motility of the small intestine. An electro cardiogram revealed evidence of myocardial damage. A dextrose tolerance test after oral administration of 100 Gm. of dextrose gave results shown in table 2 for blood sugar. In the third hour of the test the patient became strikingly pale and apprehensive, perspired profusely and complained of severe precordial pain radiating to the left arm. These symptoms were promptly relieved by orange juice.

A similar attack of hypoglycemia and angina pectoris was precipitated one month later by the insulin test. The curve for blood sugar after intravenous injection of 10 units of regular insulin was as follows: fasting, 80 mg.; after fifteen minutes, 111 mg.; after thirty minutes, 80 mg., and after forty-five minutes, 59 mg. per hundred cubic centimeters. In the last quarter of the hour the patient again showed pallor, perspiration and severe anginal pain and had to be given orange juice. He described the character and the intensity of the pain during both tests as identical with his spontaneous attacks.

TABLE 2.—*Dextrose Tolerance Tests* *

* Blood sugar in milligrams per hundred cubic centimeters is shown, while figures in parentheses indicate sugar concentration in the urine in grams per hundred cubic centimeters. The other specimens of urine were sugar free.

Therapy consisted of a high protein, high fat diet, with only moderate amounts of carbohydrates, frequent feedings, liver extract and iron. Under this treatment weight increased by 3 pounds (1.3 Kg.); hemoglobin concentration rose to 79 per cent, and the general condition improved considerably. Although complaints of epigastric pressure and discomfort after meals persisted, though to a minor degree, the late postprandial symptoms of perspiration, anxiety, weakness and precordial oppression disappeared completely. The patient is now able to take his daily walk and to live a more active life.

*Comment.*—Typical postgastrectomy syndrome was observed in a 74 year old man who also presented evidence of arteriosclerotic heart disease. Attacks of angina pectoris occurred two to three hours after meals in association with symptoms of hypoglycemia. Similar attacks were reproduced in the dextrose tolerance test, as well as in the insulin test during the steep drop of the blood sugar level. Therapeutic management resulted in pronounced general improvement, relief of the "late" postprandial symptoms (two to three hours after meals) characteristic of hypoglycemia and subsidence of the anginal syndrome.

Another patient (no. 18) presented a combination of the postgastrectomy syndrome with diabetes mellitus, which will be discussed later.

### LABORATORY FINDINGS

Laboratory studies included blood counts and blood protein content, gastric acidity and, especially, a careful investigation of the alterations of carbohydrate metabolism. Vitamin A studies were performed in 12 patients. These studies consisted of the analysis of the fasting level of vitamin A and carotene and of the vitamin A tolerance test after oral administration of 180,000 international units of vitamin A in oil.

*Blood Counts and Protein Content.*—Only occasional abnormalities were encountered in the morphologic blood studies. The red blood cell count averaged 4,397,000 (range 3,620,000 to 5,620,000). The average hemoglobin concentration was 81 per cent (range 68 to 101 per cent). A moderate secondary anemia of the hypochromic type was observed in patients 3, 12, 17 and 18. The white blood cell count was essentially normal in the group.

The average protein content was 6 Gm. per hundred cubic centimeters of serum (range 4.6 to 7.4 Gm.), which is a low normal level for the average hospital population. The average albumin concentration was 4.2 Gm. per hundred cubic centimeters (range 3.1 to 5 Gm.); the average globulin concentration was 1.6 Gm. per hundred cubic centimeters of serum (range 1 to 2.5 Gm.). Hence, blood proteins, as well as blood protein partition, were in normal limits.

*Gastric Contents and Roentgenographic Studies.*—The gastric contents were examined in 19 patients. The test meal administered to 14 patients consisted of 150 cc. of a 5 per cent alcohol solution; 3 patients were given 60 Gm. of white toast and 200 cc. of water; 1 patient was given gruel and 1 patient bouillon. The gastric contents were collected for two hours at fifteen minute intervals. Thirteen patients showed absence of free hydrochloric acid, and in the remaining patients the figures varied from traces to 32 units of free hydrochloric acid. Total acidity ranged from 8 to 42 units. A careful search was made in order to correlate presence or absence of free hydrochloric acid with occurrence of hypochromic anemia. However, no definite relationship existed between these factors. While 1 patient with hypochromic anemia showed normal gastric acidity (no. 3), another patient (no. 18) showed traces of free hydrochloric acid, and 2 (patients 12 and 17) had achlorhydria.

In all patients roentgenographic studies of the gastrointestinal tract were performed, and special attention was paid to the size of the gastric stump, the function of the stoma, the presence of an anastomotic ulcer, evidence of gastritis and the motility of both the resected stomach and the small intestine. A well functioning stoma was present in all patients, with rapid evacuation in most. At the time of the study none of the patients presented evidence of marginal ulcer. It must be mentioned, however, that in patient 10 an anastomotic ulcer developed in the later course of observation and that patient 16, prior to the study, showed an ulceration at the junction of the afferent and efferent jejunal loops (diagnosed by gastroscopy) which healed in the course of hospitalization. In many patients a distention of the efferent jejunal loop was observed. In 1 instance (patient 20) a distention of the afferent loop was observed and coincided with the early phase of the postprandial symptoms of the patient (observation of Dr. Asher Winkelstein). Detailed studies of the small intestine were performed in 9 patients. One patient (no. 17) presented the characteristic "deficiency pattern" of the small intestine with hypermotility. The other patients showed normal pattern and motility.

Analyses of the feces for presence of undigested food elements disclosed occasionally increased amounts of fatty acids and soaps in absence of neutral fat and rarely undigested muscle fibers in moderate amounts; starch digestion was in normal limits. In none of the patients was there evidence of frothy, tan, bulky stools suggestive of steatorrhea and sprue.

*Vitamin A Metabolism.*—Estimation of vitamin A concentration of the serum in the fasting state and four hours after oral administration of the test dose of 180,000 international units of vitamin A in oil was done in 12 patients. The average fasting serum level was 66 micrograms per hundred cubic centimeters (range, 42 to 108 micrograms). The average concentration after four hours was 136 micrograms (range 66 to 195 micrograms). These figures are normal for the average patient. Only in 1 instance a flat curve was observed (patient 11). Detailed data were reported elsewhere.[4]

### ABNORMALITIES OF CARBOHYDRATE METABOLISM

Abnormalities of carbohydrate metabolism are an important feature of the postgastrectomy syndrome. Fasting blood sugar was determined in all 20 patients and was followed up in 19 by dextrose tolerance tests with oral administration of 100 Gm. dextrose. In 1 patient (no. 12) the administration of dextrose resulted on repeated occasions in violent vomiting. The majority of the other patients complained of epigastric pressure and nausea shortly after the intake of dextrose, and later of dizziness and palpitations. It was necessary to place a number of them in a horizontal position to prevent vomiting.

The average fasting blood sugar (table 2) was 100 mg. per hundred cubic centimeters (range, 70 to 146 mg.). Three patients had a moderate elevation of the fasting blod sugar (patients 6, 9 and 18); in only 4 instances was the fasting blood sugar below 80 and in no instance lower than 70 mg.

The blood sugar curves tended to form early peaks, with a rapid drop after two to three and a half hours to comparatively low figures. The maximum elevation of the blood sugar ranged from 130 to 392 mg. per hundred cubic centimeters; the average was 195 mg. The maximum elevation in this group is higher than that in the previous report because of patient 18, who had diabetes mellitus in association with the postgastrectomy syndrome. With exception of this patient, who showed a typical diabetic dextrose tolerance curve, all showed definite posthyperglycemic hypoglycemia, ranging from 50 to 80 mg. per hundred cubic centimeters, with an average of 60 mg.

With the exception of the patient with diabetes, no one showed glycosuria in the fasting state. Nevertheless, 12 of the nondiabetic persons spilled considerable amounts of dextrose in the course of the test, ranging from traces to 7.5 per cent. For nondiabetic persons glycosuria of this extent in the course of the dextrose tolerance test is unusual. These observations are in agreement with reports of other authors.[5]

The history of the patient (no. 18) with postgastrectomy syndrome and diabetes mellitus is briefly summarized because of the problem encountered in the control of the diabetes.

B. Z. was a 47 year old white woman. An appendectomy was performed in 1928 and partial gastrectomy for duodenal ulcer in 1932. The original weight was 178 pounds (80.7 Kg.). Before the gastric operation it was 140 pounds (63.5 Kg.), then gradually declined to 128 pounds (58.1 Kg.). Chief complaints were weakness, fatigue, precordial pain on walking and epigastric pressure, dizziness, palpitations and perspirations one and one-half to three hours after meals. In the past two weeks she also complained of pruritus vulvae, increased thirst and polyuria. An additional loss of weight (12 pounds [5.4 Kg.]) to 116 pounds (52.6 Kg.) occurred.

On physical examination the patient was decidedly underweight; the tongue was dry and red. Blood pressure was 125 mm. of mercury systolic and 80 diastolic. A soft systolic murmur was heard at the apex. The abdomen showed an epigastric scar; no masses were palpable. The liver and spleen were not enlarged. The urine gave a 4 plus reaction for sugar. Fasting blood sugar measured 180 mg. per hundred cubic centimeters. Blood count showed 68 per cent hemoglobin and 4,090,000 erythrocytes. The electrocardiogram was within normal limits. A dextrose tolerance test performed a few weeks later showed a typical diabetic curve (table 2). In the course of the test large amounts of sugar were found in the urine. Gastric analysis showed traces of free hydrochloric acid. Roentgenographic examination revealed a comparatively long stomach stump, with rapid emptying, and a normal small intestine.

The management of the diabetes met with difficulties. On a diet of 200 Gm. of carbohydrate, 100 Gm. of protein and 80 Gm. of fat and with the injection of 20 units of protamine zinc-insulin daily, the fasting blood sugar level decreased to normal figures of 80 to 104 mg. per hundred cubic centimeters. Nevertheless, glycosuria of 2 to 4 per cent persisted. The weight increased by 5.5 pounds (2.5 Kg.). The difficulty of dietary management was enhanced by postprandial discomfort, nausea and inability to consume regular meals. The patient found through her own observation that small feedings taken almost hourly were best tolerated.

*Comment.*—In a patient with postgastrectomy syndrome diabetes mellitus developed fifteen years after operation. The condition was characterized by hyperglycemia in the fasting state, pruritus vulvae, polydipsia and polyuria and additional loss in weight. The extremely high level of the dextrose tolerance test in a comparatively mild diabetes might have been the result of the metabolic disorder, as well as of the rapid absorption of dextrose by the small intestine, as seen in other, nondiabetic persons. The management of the diabetes was difficult because of the coexisting postgastrectomy syndrome.

It is of interest that most of the patients complained during the dextrose tolerance test of gastric and general symptoms resembling those occurring after meals. These symptoms could be classified as "early" and "late" postprandial symptoms. During the first one-half to one hour of the test epigastric pressure, fulness, nausea and occasional vomiting occurred. The symptoms subsided gradually to recur later in a somewhat different form. In this phase, in the second to third hour of the test, dizziness, perspiration, headaches, palpitations and other vasomotor symptoms were the leading complaints, resembling closely the classic symptoms of hypoglycemia.

### PSYCHOSOMATIC STUDIES

The majority of patients of this group presented stigmas of psychoneurosis, with tendency to fixation and overemphasis of symptoms. It seemed easy to attribute the "nervousness" to the poor general condition and loss of weight. In careful interviews, however, psychoneurotic trends could be traced back to the period preceding gastrectomy and even the onset of the disease. The following brief summary of the history of patient 15 illustrates the relationship between constitutional and psychogenic factors, the trauma of the operation and the development of the postgastrectomy syndrome.

In E. G., a 40 year old white woman, gastric symptoms developed nine years ago. Subtotal gastrectomy was performed one year ago; since then anorexia, postprandial distention, constipation, belching, dizziness and fainting spells occurred. Her normal weight was 138 pounds (62.6 Kg.); weight before the operation was 85.5 pounds (38.8 Kg.) and at the time of study 95 pounds (43.1 Kg.). The patient looked underweight and emaciated. Results of physical examination were essentially normal, with the exception of a mitral valvular lesion. The blood cell count showed 82 per cent hemoglobin, and 3,620,000 erythrocytes. The urine showed no abnormality. Results of dextrose tolerance test are shown in table 2.

*Psychiatric Study.*—The patient's father died at the time of her birth; the mother remarried when the patient was 5 years of age. She was in her youth "a happy, contented, fat girl." She had chorea and rheumatic fever at age of 9 and was hospitalized for several months. At age of 15 she ran away from home, after a love affair was discovered by her mother. She was married at 15½ years of age. She was pregnant twice; the first pregnancy ended in abortion when she was 17 and the second in a miscarriage. She divorced her husband because of increasing friction after eight years. A period of promiscuity followed. One year later, she met a man of another faith to whom her mother objected. Disregarding this objection, she has been living since then in a common-law marriage with the man. In 1938 an operation for vaginal bleeding was performed during which a three month pregnancy was found. This pregnancy terminated later in miscarriage. In 1939 hysterectomy was carried out for fibroids. After this operation symptoms of depression and anorexia occurred, with recurring episodes of retrosternal and epigastric pain before and after meals, which were relieved by vomiting. She lost 35 pounds (15.9 Kg.) in eight years. In 1947 subtotal gastrectomy for two gastric ulcers was done. The postoperative symptoms became more intense after the recent death of her mother. Tension and apprehension increased.

*Comment.*—During the interviews it became clear that patient had considerable guilt feelings caused by the common-law marriage, as well as the abortion and miscarriages. The development of anorexia and gastric symptoms followed closely surgical castration. This operation served as atonement for the patient's guilt feelings, but it created a new conflict situation inasmuch as her desire to have children was frustrated. In the course of the interviews, patient was able to discuss her problems freely and gained some insight. Subsequently, some of the "early" postprandial symptoms improved, while the "late" complaints remained unchanged.

F.: Blutzuckerspiegel und Magenresektion, Ztschr. f. klin. Med. **120:** 692, 1932. (*c*) Beckermann, F.: Ueber spontane Hypoglykämie nach Magenoperationen, Deutsche med. Wchnschr. **59:** 683 (May 5) 1933. (*d*) Lawrence, R. D.: Glycosuria of "Lag-Storage" Type: Explanation, Brit. M. J. **1:** 526 (March 14) 1936. (*e*) Evensen.[3h] (*f*) Gilbert and Dunlop.[3i] (*g*) Barnes.[3k] (*h*) Zollinger and Hoerr.[3l] (*i*) Footnote 3m. (*j*) Adlersberg and Hammerschlag.[4]

During treatment of this and other patients it became evident that early in their lives severe repressed conflicts played an important part. The operation had the symbolic significance of punishment for unconscious guilt feelings. The postoperative course *per se*, as well as the postgastrectomy symptoms, added insult to injury and certainly contributed to the development of an outspoken postgastrectomy syndrome. These symptoms created a considerable amount of uneasiness and anxiety, which frequently led to the fear of eating, with consecutive further deterioration of nutritional status. Thus, a vicious circle was perpetuated, in which the postprandial symptoms and the fear to eat were important factors.

The final clinical picture of a severe case imitated, both physically and psychologically, that of anorexia nervosa: a morose, self-centered, underweight patient with deeply set eyes and diminished cutaneous turgor, full of anxiety centering especially about the gastrointestinal tract. The low basal metabolic rate may well fit in, as seen in patient 4, whose basal metabolic rate was —11 to —19 per cent.

### PROPHYLAXIS AND THERAPY

Opinion is divided concerning prophylaxis of the postgastrectomy syndrome. Preoperative testing has been recommended for orthostatic hypotension in order to eliminate patients with "unbalanced vegetative nervous system" who may be candidates for the postgastrectomy syndrome.[31] In our opinion, patients with peptic ulcer, especially duodenal ulcer, who present a tendency to hypoglycemia, may be considered poor risks for subtotal gastrectomy; preoperative dextrose tolerance tests may prove advantageous. Corrections in operative technics have been suggested, e. g., changing from Billroth II to Billroth I,[31] or abandonment of the retrocolic Polya anastomosis in favor of a modified Hofmeister type of anastomosis,[31] while other authors attributed less importance to the employed surgical procedure.[31] Ogilvie summarized his opinion as follows:

> These requirements are satisfied by . . . (if we must have names, let credit be properly attributed) the high posterior Finsterer-Lake-Lahey modification of the Miculicz-Kronlein-Hofmeister-Reichel-Polya improvement of the Billroth II gastrectomy with a large valve and a small stoma.[6]

Greater agreement prevails in regard to treatment. To compensate for the rapid emptying or "dumping" of the gastric contents into the jejunum, which is responsible for the early symptoms, frequent and small feedings have been recommended. The "late" postprandial symptoms are favorably affected by a high protein, high fat diet, with moderate amounts of carbohydrate and, especially, avoidance of foods and fluids of high sugar content. Thus, the treatment of the late phase of the postgastrectomy syndrome resembles that used in "primary" hypoglycemia. We wish to stress the high protein content of the diet as an essential therapeutic factor. The slow and gradual release of carbohydrate from protein results in a moderate elevation of the blood sugar level and so prevents the secondary hypoglycemia. In addition to dietary management, administration of olive oil before meals,[31] ephedrine,[31] or atropine[7] has been recommended. In our experience, dietary management supplemented with vitamins and liver extracts resulted in symptomatic improvement and occasional gain in weight in some of the patients, while the majority was strikingly resistant to therapy. Atropine increased rather than relieved the discomfort. No reports are available as yet concerning the effect of vagotomy on the postgastrectomy syndrome. It may be mentioned, however, that patient 20, who underwent vagotomy and subtotal gastrectomy at the same time, had one of the severest cases of the group.

Recently, in our hospital, psychotherapy has been added to the management of the postgastrectomy syndrome. It may favorably affect the tension of the patients and thus lead to improvement of the somatic symptoms. It was of interest to note that only the "early" and not the "late" postprandial symptoms responded to psychotherapy.

### COMMENT

Clinical analysis of the symptoms encountered in 20 patients with partial gastric resection for peptic ulcer permitted a classification into "early" and "late" postprandial symptoms. The early symptoms were: epigastric pressure, nausea and fulness, eructation and belching, dizziness and occasional vomiting. These symptoms could be observed during eating, immediately after the meal or sometimes after a short interval. The late symptoms, occurring usually in the second or third hour after meals, were: headache, fatigue, weakness, perspiration, palpitation, dizziness, shortness of breath and, occasionally, precordial pressure. The change from vertical to horizontal position resulted sometimes in relief of the early as well as the late symptoms, so that some patients acquired the habit of resting after meals. Another difference between the early and the late symptoms was the response to eating: while the late symptoms were relieved by food, the early symptoms precluded any additional food intake.

The difference in the character and mechanism of the early and late postprandial symptoms[4] was confirmed by additional observations. One gained the impression that after partial gastrectomy many more patients experienced early postprandial symptoms similar to those encountered in our group. In the normal postoperative course, the majority showed some form of adaptation to the altered mechanism of digestion and became asymptomatic. Fortunately enough, only a comparatively small group retained the early postprandial symptoms for many years. In contrast, in many persons the late postprandial symptoms gradually developed in the later postoperative course, not infrequently many months or even years after gastric resection. The difference in the development of the early and late postprandial symptoms suggests different mechanism. Zollinger and Hoerr[31] confirmed our observation that two distinct syndromes must be differentiated, one appearing shortly after the ingestion of food, the other after a latent period of one hour or longer.

We are inclined to attribute the early postprandial syndrome to mechanical factors of the small stomach, with its rapid emptying, rapid filling and distention of the jejunum and the subsequent mesenteric iritation. Gastritis of the stump or especially of the stoma, as well as jejunitis, may be predisposing factors. The operative technic may have some bearing. In this connection filling and distention of the afferent loop, as observed in patient 20, should be mentioned. The importance of this factor is questionable.[2] It is difficult for us to understand that hypoglycemia as such may explain this phase of the postgastrectomy syndrome as Gilbert and Dunlop assumed.[3l]

[7] Glaessner, C. L.: Hyperglycemic Shock, Rev. Gastroenterol. 7:528 (Nov.-Dec.) 1940.

There is no evidence, on the other hand, that hyperglycemia *per se* can produce epigastric discomfort and occasional vomiting, as suggested by Glaessner ("hyperglycemic shock").[7] We emphasized in the previous publication that there is no other instance known in which hyperglycemia would lead to similar symptoms of shock[4]; Zollinger and Hoerr,[3l] Portis[8] and Gilbert and Dunlop [3l] shared this opinion.

The late postprandial symptoms are closely related to chemical factors, i. e., to the rapid and steep decrease in the blood sugar level. The clinical manifestations closely resemble typical hypoglycemia and are relieved by food. An additional confirmation is found in the experimental reproduction of the late postprandial symptoms of palpitation, perspiration and dizziness during the hypoglycemic phase of the dextrose tolerance test. The occurrence in patient 17 of attacks of angina pectoris several hours after meals, as well as during the late phase of the dextrose tolerance test and also after administration of insulin, illustrates this mechanism.

It is important to consider, however, that symptoms of hypoglycemia are not infrequently observed in ulcer patients not operated on, and occasionally in apparently normal persons.[3a-c] Evensen observed hypoglycemic symptoms in 30 per cent of his patients with gastroenterostomy, in about 15 per cent of patients with resected stomachs, in 8 per cent of patients with peptic ulcer not operated on and in 6 per cent of normal persons.[3h] Winkelstein and Hess observed a higher response to insulin in patients with duodenal ulcer than in normal persons and assumed an increased nuclear vagal irritability in the former.[9]

One has the impression that severe cases of the postgastrectomy syndrome are bound to occur in a group of persons who already before the operation have a tendency to hypoglycemia. Preoperative dextrose tolerance tests may prove helpful in singling out these persons as "poor operative risks" for gastric resection. In the postoperative course, these patients may acquire an additional sensitivity to hypoglycemia. Whether prolonged recurrent hyperglycemia results in the production of larger amounts of insulin, whether abnormal sensitivity to insulin develops, or whether the anti-insulin mechanisms (pituitary, adrenals) are insufficiently mobilized to counteract the rapid fall of blood sugar cannot be decided. On the basis of insulin-dextrose curves and epinephrine sensitivity tests, Barnes assumed that increased sensitivity to insulin is the main factor.[3h] It must be stressed, however, that not only the actual blood sugar level, but the rate and extent of the fall are of importance (Lawrence's "oxyhyperglycemia").[10]

Factors other than increased insulin sensitivity must also be considered. In our opinion, the posthyperglycemic hypoglycemia after gastrectomy is caused by a multiplicity of factors. The rapid elevation of the blood sugar level *per se*, caused by the rapid emptying and absorption by the small intestine, is one of them. This factor was responsible for the difficulty in management of patient 18, who had diabetes mellitus and had undergone partial gastrectomy. The tendency of ulcer patients to hypoglycemia is another factor. Abnormality of the insulin: anti-insulin balance, as well as abnormal psychologic response to hypoglycemia, may be an additional factor. Since the preceding diet is known to affect the character of the dextrose tolerance curves, ulcer diets, which are, as a rule, high fat diets, used prior to the test may be another factor responsible for the abnormal pattern.

In isolated instances patients of this group presented a syndrome of dyspnea, palpitations and headaches, which could be interpreted as anaphylactic shock. It must be considered that mechanically and physiologically altered digestion may occasionally lead to absorption of unchanged protein with the subsequent effect of anaphylaxis and shock. Observations of urticaria and other cutaneous manifestations, as well as intolerance of certain foods (milk, eggs), after partial gastrectomy may well represent anaphylactic or allergic phenomena.[11]

In this group of patients only occasionally large amounts of unabsorbed fatty acids and soaps and moderate amounts of undigested muscle fibers were discovered in the stools, while no evidence of disturbed starch absorption was observed. Although none of the patients presented steatorrhea resembling sprue, in one instance a flat vitamin A tolerance curve, as found in sprue, was encountered. This observation indicates that disturbed intestinal absorption may be a factor which should not be overlooked.[12] These changes are apparently more pronounced after total gastrectomy.[13]

## SUMMARY

The symptoms encountered in a group of 20 patients who, after partial gastrectomy for ulcer, presented difficult nutritional problems, are divided into two groups: "early" and "late" postprandial symptoms. The early symptoms are epigastric pressure, nausea and fulness, eructation and belching, dizziness and occasional vomiting. They are attributed to mechanical factors: distention and rapid emptying of the small stomach and overflooding of the small intestine. Gastritis of the stump as well as jejunitis may be predisposing factors. The late symptoms are headaches, fatigue, weakness, perspiration, palpitation, dizziness, shortness of breath and, occasionally, precordial pressure. These symptoms are attributed to chemical factors: hypoglycemia secondary to the exaggerated postprandial hyperglycemia. The possibility of increased insulin sensitivity is discussed.

The postgastrectomy syndrome is caused by a combination of these factors with distinct psychoneurotic disturbances. The postoperative course, as well as the postgastrectomy symptoms, adds insult to injury and contributes to the development of a vicious circle, wherein the postprandial distress and the fear to eat are outstanding factors. The clinical, nutritional and psychologic aspects of treatment of these patients, frequently involving great difficulties, as well as the possibility of prophylaxis, are discussed.

## ABSTRACT OF DISCUSSION

Dr. Ralph Colp, New York: The opponents of subtotal gastrectomy have stated that following this procedure many patients fail to gain weight and show a symptom complex which has become known as the postgastrectomy or "dumping" syndrome. In my experience with gastric resection for peptic ulcer, this complication has not been frequent. When it has occurred it has been extremely difficult to treat successfully. Dr. Adlersberg and Dr. Hammerschlag presented an excellent study of the early and late symptoms, and of the mechanism of the postgastrectomy syndrome in 20 cases. It would be highly desirable to avoid surgical intervention in those patients in whom the postgastrectomy syndrome might develop, but since surgery is concerned only with medical failures, what else can be done for these patients suffering from intractable pyloric stenosis and recurring episodes of severe hemorrhage? Moreover, it is extremely doubtful that patients with duodenal ulcer and a preoperative tendency to hypoglycemia should be considered poor risks for subtotal gastrectomy. More than likely, similar symptoms would develop in this group from a gastroenterostomy, in addition to possible subsequent gastrojejunal ulceration. Even vagotomy as a solitary procedure, while it may not be followed by the "dumping" syndrome, may have other postoperative features almost as undesirable. I feel reasonably certain that the type of technical procedure employed in subtotal gastrectomy by experienced and competent surgeons plays little or no role in the incidence of the "dumping" syndrome, for all clinics, each with a special technic, have encountered this train of postoperative symptoms. The early postprandial symptoms referred to by the essayists are not infrequent. They are undoubtedly due to mechanical factors incident to operation and are spontaneously corrected by gradual adaptations to the altered gastric physiologic function. Frequent small feedings usually allay the symptoms. It is the treatment of the late postprandial complications which presents a challenge. In the majority of these cases, as the authors showed, the syndrome is probably the result of a rapid and sharp decrease of the blood sugar levels. Unfortunately, the cause of this hypoglycemia is still obscure. In an attempt to correct the hypoglycemia secondary to an exaggerated postprandial hyperglycemia, Dr. Adlersberg and Dr. Hammerschlag used a diet high in protein content supplemented with vitamins and liver extract. They candidly stated that the majority of these patients are resistant to therapy. This strikes a sympathetic chord in the surgeon who has seen a few of these unfortunate persons remain miserable despite all therapeutic efforts, even psychotherapy.

Dr. Joseph B. Kirsner, Chicago: One of the most curious aspects of this syndrome is its apparently low incidence. Undoubtedly, more cases would be discovered on closer observation. The question remains, however, as to why some patients are susceptible and others are not. One explanation is the increased production of insulin and abnormal sensitivity to it. Some of you may recall the complete study of 3 patients in whom a total gastrectomy had been performed, with no symptoms of the type described. Although hyperglycemia occurred early in the oral dextrose tolerance test, hypoglycemia did not develop subsequently. The psychogenic component mentioned by Dr. Adlersberg may be a determining factor. Emotional states are present in many cases and they contribute significantly to the symptoms. In the light of these considerations, it would be desirable to investigate not only patients with symptoms but also persons without distress after gastric resection, using the same methods of study employed by Dr. Adlersberg, so as to determine significant differences and precipitating factors. I think the classification of early and late symptoms and the differentiation of the mechanisms involved are helpful not only in understanding this syndrome but also in providing a rational basis for therapy. With regard to the mechanism of the late symptoms, it may be of interest to recall that Kalk in 1932 apparently reproduced the syndrome in a normal subject by means of intrajejunal intubation and alimentation. I noted in Dr. Adlersberg's series 1 patient in whom a vagotomy had been performed in addition to gastric resection. The question, therefore, may be raised: What role do the vagus nerves play in this syndrome? As a matter of fact, similar symptoms have been noted in patients with gastrectomy and vagotomy, in persons with vagotomy and gastroenterostomy, and, indeed, in patients subjected only to vagotomy. It seems apparent, therefore, that the vagus nerves and so-called vagotonia play no role in the pathogenesis of this syndrome. I also have been impressed with the difficulty in restoring the weight of patients following gastrectomy. This may be attributed to faulty absorption of food, occasioned by rapid passage through the bowel. Abnormalities in absorption undoubtedly are important in the pathogenesis of the postgastrectomy syndrome.

Dr. Otto Porges, Chicago: Dr. Adlersberg and Dr. Hammerschlag observed a new point in the postgastrectomy syndrome as far as the differentiation between early and late symptoms is concerned. The late symptoms, according to their opinion, are caused by hypoglycemia. The observation that the syndrome may depend on hypoglycemia was published fifteen years ago by Lapp and Dibold. At that time I checked this theory and observed that the symptoms and complaints of the patients coincide with the early postprandial time when the blood sugar level is either elevated or normal. The most important phase of the syndrome is the early postprandial time. Furthermore, twenty years ago I studied this syndrome and described it in conection with my papers about what I called enteritis or jejunitis. Dr. Adlersberg was my student at that time, and he may recall these studies. He may know that the signs of enteritis which I described are to be seen in postgastrectomy patients just as well. But I have seen patients without gastrectomy who had enteritis, and they showed these same symptoms which have been described as postgastrectomy syndrome. In those cases a distention of the jejunum does not play a part either because, as I ascertained, there was normal filling of the stomach and small intestine. Therefore, the most important factor in the postgastrectomy syndrome is jejunitis, and the jejunitis, of course, is caused by indigested food that damages the small intestine. If one treats the jejunitis accordingly, one can relieve the distress and the patient can be cured.

Dr. Thomas E. Machella, Philadelphia: I shall confine my remarks to the symptoms of the "dumping" syndrome which occur at the end of a meal or shortly thereafter. During the past six months my colleagues and I studied 15 such cases. The symptoms manifested during the early postprandial period were similar to those reported by Dr. Adlersberg as occurring during the late postprandial period. They could be reproduced by inflating a balloon in the jejunum; in other words, by mechanical distention. However, mechanical distention of the jejunum by the bulk of a meal itself fails to explain why some meals produce symptoms while others of equivalent volume do not. This fact led us to suspect that a physical property, perhaps the osmotic pressure, of one or more constituents of a meal determined whether or not symptoms occurred. Our suspicions were confirmed when we were able to reproduce the symptoms in normal subjects and in postgastrectomy patients by the introduction into the jejunum of not only hypertonic glucose and sucrose solutions but also sodium sulfate, magnesium sulfate and amino acid mixtures. Such solutions increase in volume by dilution and thus distend the intestinal loop to produce symptoms. The administration of atropine in physiologic doses about an hour before a mixed meal prevented "dumping" symptoms in 14 of our patients. They were not prevented, however, by vagotomy.

Dr. H. Necheles, Chicago: Dr. Adlersberg proposed the term "postgastrectomy syndrome." I do not think that term describes the picture too well because it includes anemia, marginal ulcer and a number of other observations. I think the condition should be called "postprandial syndrome," which may be subdivided into "early" and "late" postprandial syndrome. When my associates and I compared the results of intravenous and oral dextrose tolerance tests in a group of patients with postprandial syndrome, we found to our surprise that the results of the intravenous tests were normal; as a matter of fact the curves for all intravenous dextrose tolerance tests were similar. There was little or no hypoglycemia within two hours, and no early or late postprandial symptoms were observed. With the oral dextrose tolerance tests, we saw early and late symptoms. Blood sugar levels rose higher than normal, followed by hypoglycemia down to 20, and in 1 case to 17, mg. per hundred cubic centimeters. We also performed oral fructose tolerance tests and observed distinct early postprandial symptoms, unrelated to blood sugar levels. The theory of hyperglycemic shock of Glaessner and Winkelstein and Hess is untenable in our opinion. We also tested the effect of atropine on the postprandial syndrome. It modified the early but not the late symptoms, and it did not abolish hypoglycemia. We also performed tests in which we used saccharin instead of dextrose, but we found no postprandial symptoms and no effects on the blood sugar. We know that under stress the autonomic nervous systems, sympathetic and parasympathetic, go into action. Thus, when a patient is apprehensive, and when an inflamed gastrojejunal mucosa is irritated, hyperglycemia may follow, due to sympathetic reflexes and to epinephrine. These sympathetic manifestations overshadow the parasympathetic effects. When the sympathetic effects decrease, parasympathetic stimulation may become evident, and hypoglycemia may be due in part to vagal activity. Therefore, the early and late postprandial symptoms are somewhat complicated by the reactions of both autonomic nervous systems.

Dr. Hyman I. Goldstein, Camden, N. J.: In his list of pioneer operations on the stomach, Dr. Adlersberg omitted that of Jules Péan, French surgeon, who performed the first (April 5, 1879) gastric resection for cancer of the pylorus (*Gaz. de hôp.*, Paris **52**:473-475, 1879; *Bull. Acad. de méd.*, Paris, Section 2 **8**:1194-1197, 1879). Billroth did his first pylorectomy in 1881 (*Wien. med. Wchnschr.* **31**:161-165, 1881; **33**:1213-1215, 1883; **34**:880-890, 1884). Dr. Adlersberg will be interested in the successful gastrotomy performed by the lithotomist Daniel Swabe (or Schwalbe) who operated on the peasant André Grundheide July 9, 1635—probably the first successful gastrotomy—unless prior credit be given to Master Florian Matthis for his successful gastrotomy in 1602! At the temple of Aesculapius at Epidaurus, Greece, six pillars engraved with the stories of patients date from the close of the fourth century B. C. On the second pillar appears case 7: "A man with an ulcer in his stomach. He incubated and saw a vision; the god seemed to order his followers to seize and hold him, that he might incise his stomach. So he fled, but they caught and tied him to the door knocker. Then Aesculapius opened his stomach, cut out the ulcer, sewed him up again and loosed his bonds. He went away whole, but the floor of the chamber was covered with blood." This is probably the earliest reference to a gastric resection for ulcer of the stomach, although Diocles circa 350 B. C.) described the typical symptomatology of peptic ulcer, as quoted by Galen (130-201 A. D.)! I hope no overenthusiastic young surgeon, after hearing Dr. Adlersberg's presentation, will do subtotal gastric resection or vagotomy for the treatment of diabetes!

Dr. David Adlersberg: The proper selection of patients with peptic ulcer for gastrectomy, or vagotomy, or partial gastrectomy plus vagotomy, or gastroenterostomy plus vagotomy, is a problem that must be solved in future studies. We venture to say that vagotomy is not the answer for the treatment of the postgastrectomy syndrome. Our group of patients was presented for discussion because of the difficulties encountered in managing them. In many instances, the body weight of the patients was 90 to 100 pounds (40.8 to 45.4 Kg.); they were cripples, unable to eat, work or gain weight. During an observation period of one to five years, and despite various types of diet, liver and vitamin medication, and more recently, psychotherapy, the therapeutic results were, as a whole, unsatisfactory. The most extensive study of carbohydrate metabolism in peptic ulcer, after gastroenterostomy and after gastric resection, was done by Evensen. Hypoglycemia is not infrequently observed in patients with peptic ulcer, especially duodenal ulcer, and occasionally in apparently normal persons. I should like to emphasize that the complex symptoms of these patients are caused by a combination of factors rather than by one. Mechanical factors, inflammatory changes of the stomach and small intestine (gastritis, jejunitis), chemical alterations and psychologic motives must be considered. I read recently Dr. Machella's studies, but our results with atropine in the treatment of the postgastrectomy syndrome were not satisfactory. The complaints of the patients were enhanced by a dryness of the mouth and throat. Dr. Necheles' observations on the effect of oral and intravenous administration of glucose are interesting, and we look forward to his publication on this subject.

# CURE OF CHRONIC VIVAX MALARIA WITH PENTAQUINE

L. T. COGGESHALL, M.D.
and
FRED A. RICE, M.D.
Chicago

The treatment of malaria has been characterized by failure to obtain permanent cure in many cases, in spite of the fact that either quinine or quinacrine hydrochloride ("atabrine *di*-hydrochloride") will afford prompt relief of the acute attack. Post-treatment recurrences or relapses occur in a high percentage of patients with vivax and quartan malaria particularly.

During World War II an intensive research program was inaugurated to discover a curative nontoxic drug which could be administered in a practical manner. This program was conducted under the auspices of the National Research Council with many participants. Although many new compounds were discovered, the present report is concerned only with pentaquine (8-[5-isopropylaminoamylamino]-6-methoxyquinoline).[1] Highly successful results were obtained following its use in the treatment of 185 vivax-infected ex-servicemen after all other known methods of therapy had failed.

Pentaquine was synthesized by Drake [2] and was first shown to possess highly antimalarial curative properties in man by Alving and co-workers.[3] It is a derivative of the longer known pamaquine naphthoate ("plasmochin"), which some workers stated was capable of reducing the relapse rate in vivax malaria. However, because of its toxicity, pamaquine naphthoate was removed from usage for the military servicemen. Careful studies in animals and man revealed that pentaquine was a definite improvement, as it was not as toxic as pamaquine naphthoate and had considerably more therapeutic activity. One curious feature of its curative activity was the necessity for simultaneous administration of quinine. Alving and co-workers reported that a dosage of 2.0 Gm. daily of quinine taken concurrently with 60 mg. of pentaquine for fourteen days was sufficient to cure a high percentage of patients infected naturally with a strain of South Pacific malaria. This dosage of pentaquine was attended by sufficient toxic reaction to require hospitalization. It must also

be emphasized that the cures occurred in prisoners who had volunteered as subjects under the condition that they be treated early in the initial attack or first relapse. As such, they were probably much more resistant to therapy than those who had acquired specific immunity by virtue of repeated attacks. With this possibility in mind, an attempt was made to cure the infected ex-servicemen by decreasing the dosage of pentaquine to 30 mg. daily, which would reduce the likelihood of toxic symptoms and allow the patient to remain ambulatory.

### MATERIAL AND METHODS

*Subjects.*—The present study was initiated in July 1946 and only men whose blood smears were positive for malaria parasites during a relapse were treated. This was necessary to rule out the possibility of a spontaneous cure. To date, 185 subjects have been treated, of whom 170 have been followed for six months or longer and 15 for approximately four months. The infection in each was diagnosed as vivax malaria. In this group, 154 had acquired their malarial infection in the Southwest Pacific, 14 in the Orient, 7 in the Mediterranean area and 3 in the West Indies. In 2 patients malaria resulted from blood transfusions and in 5 the source was unknown. The histories showed that the number of relapses prior to treatment with pentaquine varied from 1 to 50, although these data cannot be considered reliable, as most of the patients could not recall the exact number. Also they subjected themselves to therapy at the first symptoms referable to malaria, thus undoubtedly aborting many relapses. However, there was little doubt about the date of the initial attack—6 gave 1942 as the year; 34 initial attacks occurred in 1943, 34 in 1944, 56 in 1945, 21 in 1946, 4 in 1947 and 1 in 1948. For 29 patients the date was unknown. Many of them experienced their first attack in the United States after their return, usually after discontinuing suppressive therapy. Another significant and consistent point was that practically all the subjects from the Southwest Pacific area stated that relapses occurred regularly every four to six weeks.

An attempt was made to evaluate previous therapy, but lack of sufficient records and poor memory gave little information other than that quinine, quinacrine hydrochloride, chloroquine diphosphate, arsenicals and pamaquine naphthoate had been used. "Atabrine" was most commonly used. Within the past two years, many had taken and preferred chloroquine, since it was less troublesome, although it did not result in cure or diminish the number of attacks.

*Dosage.*—As stated previously, in the present investigation the dosage of pentaquine was 30 mg., or 1 tablet, three times daily. This was given simultaneously with 2.0 Gm., or 2 tablets, of quinine sulfate three times daily. Both were administered for fourteen days. Since the amount of quinine was chosen arbitrarily and because many of the first patients treated complained of symptoms of cinchonism, the amount given was reduced to one-half, or 1.0 Gm. per day. This reduced dosage was given to 67 patients in the latter part of the study.

### RESULTS

*Toxicity.*—Initial daily and then weekly blood counts revealed no abnormalities except a minor lowering of the red cell count. Since all treatments were initiated during an acute relapse, it was not possible to ascribe the anemia to the drug, as the degree of the change was compatible with that usually observed during an infection. Only 4 men of the 185 refused to complete the therapy, the reason given being gastrointestinal upset. Forty-three of the patients had some toxic reaction. The predominant complaints were tinnitus, dizziness, gastrointestinal cramps and deafness, chiefly attributable to the quinine. In 1 patient an apparent drug rash developed on the second day of the treatment, but he subsequently completed the full course with no recurrence of the rash. One Negro who was treated had no blood or other changes. This incidental comment is given because there is information that hemolytic crisis has occurred in 2 subjects of that race following use of pentaquine.

*Relapses.*—Of the 185 patients treated, there were verified failures in 10, with blood smears yielding organisms, and 10 more had chills but no parasites could be detected in their blood smears. From the reports to date, the dosage of quinine when decreased from 2.0 to 1.0 Gm. seemed to be just as effective.

*Subjective Symptoms.*—Although 163 of the 185 had no further objective findings referable to malaria, of considerable significance to us were the enthusiastic reports from the subjects or their physicians concerning the striking relief from the subjective symptoms associated with chronic malaria. Immediate and significant gain in weight was noted in 46 men, in some cases 25 to 30 pounds (11.3 to 13.6 Kg.). Many noted the disappearance of persistent headaches which previously had not responded to any therapy. Practically all commented on an improved feeling of general well-being.

### SUMMARY

1. Pentaquine, 30 mg. daily, and quinine, 2.0 Gm. daily, later reduced to 1.0 Gm. daily, taken simultaneously for fourteen days, have resulted in the termination of relapsing vivax malaria in 163 of 185 infected ex-servicemen, although the majority were experiencing relapses every four to six weeks prior to treatment.

2. The therapeutic regimen was an ambulatory one and did not require interruption of normal activities.

3. Toxic reactions encountered were not sufficient to cause concern and were largely those commonly associated with the use of quinine.

---

## ABSTRACT OF DISCUSSION

Dr. Alf S. Alving, Chicago: As Dr. Coggeshall told you, pentaquine, which is closely related chemically to pamaquine naphthoate ("plasmochin"), is the only other drug beyond the experimental stage that has definite curative properties in vivax malaria. Pentaquine is at least as effective as pamaquine and is less toxic. The toxicity of pamaquine and pentaquine at dosages of 30 mg. per day is usually slight. The ordinary symptoms, such as abdominal pain and even neutropenia, which sometimes occur in dosages of 60 mg. of either drug, are seldom serious. The most dangerous toxic symptom is the effect on the red blood cells. In about 5 per cent of Negroes or persons of mixed racial extraction to whom pamaquine is administered in dosages as low as 30 mg. per day hemolytic crises develop. Acute hemolytic anemia is less frequent in the white group, but does occur. With pentaquine this dangerous complication appears to be less frequent. It has not been observed below a dosage of 60 mg. However, when it does develop, the drug must be stopped immediately. Therefore, these drugs must be used with caution. The margin between their effective therapeutic dose and their toxic dose is relatively small. The differences between therapeutic results obtained in heavily infected "nonimmune" white volunteers at Stateville Penitentiary and in the patients that Dr. Coggeshall has reported on are probably due to greater immunity of his patients; but the factors of strain, susceptibility and sporozoite dosage cannot be excluded. There is no question, however, that the dosage of pentaquine required for cure of the experimental infection is greater than that required in most instances of naturally acquired infection. The usefulness of pentaquine will primarily be limited to persons who have returned from endemic areas and who are going to live in places where chances of reinfection are very low. A curative drug, to be effective in the field, should also have suppressive properties because reinfection is almost certain. Pentaquine is too toxic to be used for chronic suppression of malaria but may have limited value in the field. In small nontoxic dosages it abolishes gametocytes of both falciparum and vivax malaria. The abolition of gametocytes will prevent spread of the infection from man to mosquito.

DR. L. T. COGGESHALL: In regard to anemia, 40 per cent of the cases were observed in our own laboratory. The daily red blood cell counts and hemoglobin determinations revealed no more anemia in the patients treated with pentaquine than one encounters in acute attacks of malaria. There was great relief from one subjective symptom. One of the most annoying symptoms to patients with chronic malaria is the recurrence of severe intractable headaches. We found that on giving pentaquine not only did the relapses no longer occur, but, according to many patients, for the first time in several years the headaches no longer existed. Regarding immunity of these patients, we selected a group of 21 patients who were treated with the drug, and in an attempt to prove they had been cured they were reinoculated with a homologous strain. These patients had been treated from three months to two years prior to reinoculation, and in each instance malaria developed on reinoculation; thus cure had been accomplished also. Once the infection has been eradicated in human malaria the immunity is of exceedingly short duration.

# EMERGENCIES ENCOUNTERED IN THE NEONATAL PERIOD

M. HINES ROBERTS, M.D.
Atlanta, Ga.

Emergencies encountered during the newborn period are many and varied. An attempt to discuss in detail all of the hazardous situations met during this critical period would require far more space and time than are allotted to this brief paper. Table 1 is an attempt to classify these conditions on an etiologic basis. A glance at this formidable list emphasizes the fact that one must choose those conditions which promise most profitable discussion. It seems logical, then, to devote the major portion of this paper to a few of the most commonly seen pathologic conditions. A review of neonatal mortality studies published recently indicates that relatively few diseases account for most of the deaths during this period.

Table 2 is a composite study of such reports.[1] It emphasizes the fact that the four chief causes of death are: (1) prematurity, (2) anoxia, including the various diagnoses (atelectasis, asphyxia and pulmonary deaths), (3) trauma, resulting chiefly in intracranial injury, and (4) congenital anomalies. Other less frequently encountered emergencies will be briefly discussed, namely, infection, blood loss and adrenocortical aplasia.

Table 3 is a statistical study of the neonatal deaths as diagnosed clinically or by autopsy in 17,421 living Negro babies weighing more than 1,000 Gm., born at the municipal hospital in Atlanta. These figures, in the main, are in agreement with the statistics presented in chart 2. However, there are some interesting and rather striking differences which are apparently attributable to race. The number of deaths due to anomalous development are considerably lower than most figures published for this age group. A more detailed examination of the anomalies encountered among these Negro infants will be given later, when deaths due to developmental error are discussed in detail. Even more striking is the fact that only 1 case of erythroblastosis was observed throughout the seven year period during which these statistics were collected. The high incidence of prematurity is striking and has a devastating effect on mortality statistics, as shown in the extremely high occurrence of intracranial injury.

## PREMATURITY

Prematurity can hardly be classified as an emergency except in those infants exhibiting anoxia and in a not inconsiderable number who show evidence of acid-base imbalance. For these reasons and for lack of space the discussion of the care of premature infants will be omitted, although much of what will be written later regarding asphyxia and intracranial injury is definitely applicable to this group of patients.

## ANOXIA

Undoubtedly, the most frequently encountered emergency in the neonatal period is that of oxygen want. Although many causative factors are involved, asphyxia and atelectasis are the chief concern. Resuscitation of the asphyxiated newborn infant still remains primarily in the province of the obstetrician, although the pediatrician and anesthesiologist have made valuable contributions. This is as it should be. Except in certain of the large teaching centers the obstetrician and his staff are the persons immediately on hand and therefore are the ones who must administer the lifesaving measures.

Flagg's[2] classification of asphyxia seems to be the one of most practical value from the therapeutic point of view. Table 4 presents this general outline. If such a classification be kept constantly in mind, the indications for certain types of therapy become immediately obvious and, on the other hand, one is much less prone to institute certain drastic types of resuscitative measures which, if the baby be so classified, are clearly contraindicated.

Little and Tovell[3] have given a definitive résumé of important opinions held by various workers on the subject, with an extensive bibliography. I shall borrow freely from their work in my discussion.

The technics of resuscitation vary considerably. However, there are certain basic principles on which all are agreed: first, the patency of the air passages must be maintained, and, second, oxygen must be delivered to the lungs. The methods by which these goals are accomplished are subject to controversy.

Table 5 is taken from the work of Flagg and the review by Little and Tovell. Included are uniformly accepted methods as well as certain procedures which are controversial. Among the latter may be mentioned the endotracheal catheter, which may be inserted either under direct laryngoscopy or by palpation. Opinion as to its use is variable—from that of Torpin,[4] who employs the direct method of intubation and stated that 6 to 10 per cent of infants require such resuscitation, to others who feel that the intubation of the larynx of the newborn is an unnecessary procedure and may indeed prove harmful unless employed by the most skilled persons.

In the clinic at Emory University the tracheal catheter is employed rarely, and only in the stage of flaccidity. It is introduced by palpation and not by direct laryngoscopy. The technic is mastered by the resident physician without great difficulty. We feel at times that the measure is life saving.

TABLE 1.—*Cause or Location, Emergencies Encountered in Newborn Infants*

Condition

- I Anoxia
    - Asphyxia, atelectasis
    - Obstruction of air passages: mucus, amniotic fluid, tumor, cyst, atresia, laryngeal web
    - Pulmonary disease: infection, pneumothorax, diaphragmatic hernia
    - Heart disease
- II Injury
    - Central nervous system: intracranial or subdural hemorrhage, nerve, phrenic paralysis
    - Respiratory tract: pneumothorax, hemorrhage
    - Bone: skull, vertebra
    - Endocrine: adrenal hemorrhage
- III Anomalies
    - Central nervous system; encephalocele, spina bifida, meningocele
    - Gastrointestinal tract: obstructive lesions, meconium ileus, malrotation, omphalocele
    - Respiratory tract: laryngeal stenosis, web, tracheal atresia, diaphragmatic hernia
    - Cardiovascular
    - Urinary tract: obstructions of urethra
    - Endocrine: adrenocortical aplasia
- IV Blood Loss
    - Hemorrhage: umbilical
        - Pharynx, respiratory tract, central nervous system due to injury
        - Gastrointestinal tract: ulcer, volvulus, diverticulum
    - Hemolytic anemia: erythroblastosis, congenital hemolytic anemia, sickle cell anemia
    - Thrombopenia, hypoprothrombinemia, hemopoietic aplasia
    - Infection: syphilis, sepsis
- V Infection
    - Epidemic diarrhea, sepsis, meningitis, tetanus
- VI Metabolic Diseases
    - Tetany, hypoglycemia, acidosis

Mechanical resuscitators are of doubtful value. Positive pressure up to 16 mm. of mercury with negative pressure to 9 mm. of mercury is advocated. Such pressure at times appears incapable of expanding the neonatal atelectatic lung and yet at other times seems sufficiently great to cause alveolar rupture and emphysema. Although such mechanical resuscitators are available in our delivery room, my co-workers and I depend primarily on mouth to mouth resuscitation and occasionally on the endotracheal catheter. Even these simple measures may result in damage to lung tissue, if too enthusiastically executed, without adequate care to protect the delicate alveolar sac from too great pressure. Torpin's[4] pocket insufflator with weighted valve, which controls the pressure of air or oxygen to the lungs at 20 cm. water, is a helpful adjunct, as is the simple and inexpensive apparatus designed by Graber[5] which limits the pressure of oxygen delivered to the lungs by a column of water 12 cm. deep over which the gas flows and to which the main flow is connected by a T-shaped glass tube.

The use of carbon dioxide is no longer advocated in the majority of clinics, although Henderson's[6] work still has some staunch supporters. I feel that oxygen is the primary need and that carbon dioxide is contraindicated.

Finally, drugs appear to have little, if any, value in this field. I occasionally resort to the use of epinephrine or nikethamide. I have never been convinced of their value. After an exhaustive review of the literature, Little and Tovell concluded that carbon dioxide should not be used and that drugs may do more harm than good.

The etiologic factors concerned in asphyxia are widely variable, depending on pathologic states in the mother, on abnormal conditions during labor and delivery and on pathologic conditions in the infant. A full discussion of these factors is beyond the scope of this paper; however, I would like to touch on one controversial point—the use of analgesics and anesthesia during labor. I have had the opportunity of studying the charts and seeing many of the infants delivered of mothers who have received paraldehyde in addition to meperidine hydrochloride and scopolamine. These patients were delivered at Emory University Hospital, chiefly by Dr. R. A. Bartholomew and his associates. They have permitted me to present the statistical data from approximately 2,000 such deliveries. Briefly, this routine procedure of sedation may be stated as follows: in the primipara, when dilatation has reached about 3 cm., $\frac{1}{100}$ grain (65 mg.) of meperidine hydrochloride and $\frac{1}{200}$ grain (32.5 mg.) of scopolamine are administered hypodermically. Membranes are ruptured about one hour later. Two to three hours later, when dilatation is about 5 cm., 24 cc. of paraldehyde is given by mouth. Posterior pituitary given intranasally maintains uterine contractions at 3 to 4 per minute. When crowning is complete, ether is administered during the last twenty to thirty minutes of delivery. Ninety to 95 per cent of women so treated experience complete amnesia. In the multipara, meperidine hydrochloride and scopolamine are given in a similar manner; however, membranes are not ruptured and paraldehyde is administered one-half to one hour later.

* Negroes.

† Of this number, 409, or 75.3 per cent, were deaths of premature infants.

‡ Only massive hemorrhage included.

Table 6 gives the fetal and neonatal mortality figures for 2,015 deliveries in which paraldehyde was used. It will be noted that the neonatal death rate is low, as is the stillborn figure. It must be remembered, however, that these patients come from the upper class white population and that facilities for the care of newborn and premature infants are good. These figures are in striking contrast to those presented from the Negro population, where the over-all neonatal mortality figure was above 3 per cent, almost four times as great as in the Emory University group. This high figure pertains even though the Negro mother receives no analgesic or anesthesia.

| Hemorrhagic disease of the newborn | 1 | 2 | 3 | 3 | 0.6 |
| Other diseases | 11 | 10 | 21 | 19 | 3.6 |
| Total (corrected for multiple diagnosis) | 409 | 130 | 539 | 539 | 100.0 |

* Over-all death rate in 17,421 live births, 3.09 per cent; number of premature births, 2,109; percentage of live births, 12.1 per cent. Death rate among all premature infants, 19.38 per cent.

Table 4.—*Flagg's Classification of Asphasia*

| Stage | Characteristics |
|---|---|
| Depression | Baby does not breathe well<br>Baby is capable of being aroused<br>Respiratory center, circulation, muscle tone, reflexes are all depressed from anoxia, but are easily stimulated to normal activity |
| Spasticity | Irregular, gasping, shallow respiration, occurring at long intervals<br>Marked cyanosis of mucous membrane with blotching of skin or general pallor<br>Baby's gums close on the gloved finger tip<br>Reflex reaction to aspiration of the pharynx and an active glottic reflex<br>Froth or fluid in mouth and pharynx |
| Flaccidity | Respiration at long intervals or not at all<br>Cyanosis or pallor<br>Complete flaccidity of musculature<br>Jaw completely relaxed<br>No resistance to suction or exposure of the pharynx<br>Fluid in hypopharynx<br>All reflexes in abeyance<br>Cardiac impulse may or may not be present |

It appears from this study that the use of paraldehyde does not increase infant mortality, although most observers agree that the onset of respiration may be slightly delayed and the infant may be sluggish for several hours.

It is interesting to note that the Emory University group feel that endotracheal catheterization is unnecessary. They depend almost entirely on mouth to mouth resuscitation.

### INTRACRANIAL INJURY

Intracranial injury proved the chief cause of death in our series at Emory University. As is shown in table 3, 117 premature and 78 term infants in this series died of intracranial damage—a total of 195 infants, or 36.1 per cent of the deaths. These figures pertain in a clinic in which a minimum of sedation is administered to the mother and in which operative procedure is rare; they are undoubtedly influenced by the high incidence of prematurity in the Negro race.

A reduction in neonatal mortality due to intracranial damage is primarily due to improved obstetric care. The treatment of the condition is chiefly supportive and the maintenance of adequate oxygen supply, since one of the chief causes of atelectasis is intracranial damage. In our series, of 143 pulmonary deaths due to asphyxia and atelectasis 55 showed evidence of intracranial injury; almost certainly this figure would have been higher if the percentage of autopsies had been greater.

Although vitamin K is administered routinely to premature infants, infants with respiratory difficulty and those suspected of intracranial injury, I am skeptical of its value. Hemorrhagic disease of newborn infants is rare. It was encountered only three times in our series of 17,421 Negro infants.

Spinal drainage as a therapeutic measure in intracranial hemorrhage is rarely indicated. Occasionally I have felt it of value in infants experiencing respiratory difficulty and rarely in those exhibiting convulsions. A diagnostic lumbar puncture is always indicated and, when done skilfully with a needle of proper size, does not increase intracranial hemorrhage.

The infant suffering with intracranial injury should be handled as little as possible. Our fault is one of too much rather than too little therapy—a statement which applies to many of the diseases observed during the neonatal period. Oxygen, heat, quiet and fluids, in the order named, are the chief therapeutic points to be kept in mind during the first critical seventy-two hours of life. Oral administration of fluid should be withheld until the sucking and swallowing reflexes are well established. Parenteral administration of fluid is to be avoided, if possible, because of the pain, crying and resulting engorgement of intracranial vessels. Nursing at the breast is contraindicated until the crisis is over and all danger of further hemorrhage is passed.

Table 5.—*Methods of Resuscitation (Little and Tovell and Flagg)*

I. Establishment and maintenance of the airway
   Gentle aspiration of nares, mouth and pharynx, and when needed, of the trachea and upper bronchial tree
   Aspiration of supraglottic tract before clamping the cord
   Position of fetus, 30 degree Trendelenburg
   Stage of flaccidity with collapsed glottic structures and absent reflex demand endotracheal catheter
II. Use of external stimulation
   Gentleness is stressed
III. Oxygen universally used
   Method of administration varied
IV. Carbon dioxide—controversial
V. Artificial respiration
   Mouth to mouth resuscitation
   Endotracheal catheter for suction and administration of oxygen
   Resuscitators of various types
VI. Maintenance of warmth
VII. Drugs

Table 6.—*Fetal and Neonatal Mortality in 2,015 Deliveries in Which Paraldehyde Was Used as Amnesic (Emory University Hospital, Atlanta, Ga.)*

| | Term | Premature | Total | Percentage |
|---|---|---|---|---|
| Neonatal deaths | 7 | 9 | 16 | 0.79 |
| Stillborn | 8 | 15 | 23 | 1.14 |
| Total wastage | 15 | 24 | 39 | 1.93 |

### CONGENITAL ANOMALIES

Table 7 shows the incidence of congenital anomalies which were encountered in our series. Anomalies of the heart, nervous system and gastrointestinal tract accounted for the major number of deaths. It is of interest to note the rarity of most of the important anomalies in the Negro race, especially true of the gastrointestinal tract, the genitourinary tract and the nervous system. Harelip and cleft palate occurred only eight times, or 1 in every 2,176 infants.

The early diagnosis and prompt surgical treatment of obstructive lesions of the gastrointestinal tract may prove life saving and certainly must be included among the emergencies of the neonatal period.

Vomiting is the obvious symptom. A careful study of its character may reveal much in regard to the location of the obstruction. The salient features in the clinical diagnosis of these conditions are outlined.

### TYPE OF VOMITING

1. Esophageal vomiting is of the immediate overflow type with continuous drooling of saliva and accompanied with respiratory difficulty.
2. Pyloric and duodenal vomiting is of the explosive type, showing action of the gastric musculature.
3. *Vomiting from small or large gut obstruction may be* explosive in nature, but is delayed in onset and preceded by distention from the point of atresia.

TABLE 7.—*Congenital Anomalies Encountered in 17,421 Negro Newborn Infants*

| | Number | Incidence | No. of Deaths |
|---|---|---|---|
| Congenital heart disease | 34 | 1: 512 | 20 |
| Anomalies of the gastrointestinal tract | 15 | 1:1161 | 6 |
| Anomalies of the genitourinary tract | 17 | 1:1024 | 2 |
| Anomalies of the nervous system | 22 | 1: 790 | .. |
| Meningocele encephalocele | 4 | 1:4355 | .. |
| Acephaly and microcephaly | 10 | 1:1742 | .. |
| Spina bifida | 6 | 1:2903 | .. |
| Mongolism | 1 | 1:17421 | .. |
| Amyotonia | 1 | 1:17421 | 10 |
| Hare lip and cleft palate | 8 | 1:2176 | 1 |
| Anomalies of the upper extremities | 186 | 1: 94 | 1 |
| Polydachtylism | 175 | | |
| Anomalies of the arm end hand | 11 | | |
| Anomalies of the lower extremities | 28 | | |
| Monsters | 3 | 1:5807 | 2 |
| Albinism | 1 | 1:17421 | .. |
| Total deaths | | | 42 |

### CHARACTER OF THE VOMITUS

1. The esophageal type contains mucus, sticky detritus and saliva, with immediate return of whatever fluid has been swallowed.
2. Pyloric or duodenal vomitus from above the ampulla consists of gastric contents, which are colorless, contain mucus and occasionally may be blood streaked.
3. Duodenal vomitus from below the ampulla may be greenish brown or often dark chocolate-like in appearance.
4. Vomitus from the small or large gut contains fecal or meconium-like material.

### STOOLS

Atresias above the ampulla yield normal meconium.

Atresias below the ampulla and duodenum yield stools which are grayish or white and mucoid in nature.

The result of Farber's test for squamous epithelial cells, swallowed with the amniotic fluid, is negative.

### GAS PATTERN AS INDICATED BY ROENTGENOLOGIC STUDY

Serial studies of the gas pattern in the gastrointestinal tract of the normal newborn infant indicate that the gas has reached the sigmoid and rectum by the seventh to the tenth hour.

Atresia of the esophagus usually gives a normal pattern, since there is generally a fistula between the pulmonary tract and esophagus. Opaque substance may reach the stomach and intestines by way of the lungs.

Obstructions in the duodenum and high portion of the jejunum are characteristic, showing a complete absence of gas below the distended point of obstruction. Malrotation and volvulus may simulate this pattern. Lesions lower down show evidence of obstruction, but exact location is not obvious.

In suspected esophageal lesions an attempt should be made to pass a soft catheter into the stomach. Obstruction can be immediately recognized, and further studies with an opaque substance in the upper segment of the esophagus are, as a rule, unnecessary and, indeed, are decried by some surgeons. However, the presence of a fistulous tract connecting the upper segment of the esophagus with the pulmonary tree might be overlooked without the procedure. Only iodized oil or some similar substance should be used—never a barium preparation. The latter invariably will overflow into the lung and produce pneumonia or exaggerate already existing pneumonia.

Immediate operation is indicated once the diagnosis is made. Waiting for the pneumonia of esophageal atresia to clear is a vain hope—the condition grows progressively worse.

Parenteral alimentation is an extremely important and delicate procedure. It must be done with meticulous care, *especially in the esophageal atresias.* Overhydration and excessive administration of sodium chloride may produce pulmonary edema and thus add to the infant's already difficult oxygenation. Standards for such procedures are inadequate. Most figures given for parenteral alimentation in premature and newborn infants are too high. I feel that 100 to 120 cc. per kilogram of weight in the first few days of life are adequate, including 50 to 80 cc. of isotonic sodium chloride solution each day, the remainder of fluid to be supplied in 5 per cent dextrose in water and 5 per cent amigen[8] in dextrose solution. These fluids may be administered by drip intravenously or subcutaneously. Blood and plasma are to be substituted for other fluids when indicated.

### INFECTION

Infections in our series produced relatively few deaths. Pneumonia accounted for 20 deaths, sepsis 5, meningitis 4 and peritonitis 2—a total of 31. Seven of the infants had complicating intracranial hemorrhage, making the primary cause of death obscure.

The premature and newborn infant tolerate both the sulfonamide drugs and penicillin well. The dosage of penicillin per kilogram of body weight is not definitely established. Buchanan[7] found blood levels which he believed adequate in infancy by the administration of 4,000 units per pound each twenty-four hours on a three hour schedule. It is our practice to use relatively larger doses in this age group than in later infancy and childhood, depending, of course, on the severity and type of infection. Penicillin in doses of 10,000 to 20,000 units per kilogram of body weight each twenty-four hours and sulfadiazine, 0.15 to 0.2 Gm. per kilogram of body weight each twenty-four hours, are used. In addition to chemotherapy it is essential that adequate hydration be maintained. This is especially true if the sulfonamide drugs are being given. Parenterally administered fluids are usually required, since the infants are desperately ill and take fluids by mouth poorly. Blood transfusions may prove a life-saving measure. The colon bacillus, Staphylococcus aureus hemolyticus and Streptococcus hemolyticus are particularly virulent in this age group.

Infection originating in the umbilicus extending to the liver through the umbilical vein and finally into the general circulation produces a strikingly dramatic picture. The infant may appear to progress fairly well for two or three weeks, except for a slight discharge from the navel. Occasionally this secretion has a foul odor. Then suddenly there is evidence of a profound systemic infection. Fever, cyanosis and shock rapidly appear and death has occurred within twenty-four hours of the onset of acute symptoms. Penicillin in doses of 25,000 to 50,000 units per kilogram of body weight each day may be given with no untoward effect. In case of recovery, the infant may subsequently show evidence of portal obstruction.

---

[7] Buchanan, J. L.: Penicillin in Infancy and Childhood, Lancet *2:* 561 (Oct. 19) 1946.

Epidemic diarrhea is probably the most dreaded of infections of the neonatal period. Its cause is still unknown, though a virus is suspected. No specific therapy is available, and the mortality rate remains high. From New York it is reported[8] that of 1,233 infants who contracted the disease 540 died—a mortality rate of 43.6 per cent.

Prevention of the disease by means of rigid cleanliness in the nursery, aseptic nursing technic (as nearly as this is possible) and conscientious scrubbing of the hands promises the greatest protection to these infants. Immediate quarantine of a suspected subject, isolation of exposed infants and no further admissions to the infected nursery are essential measures.

Once the disease has developed the treatment is purely symptomatic: withdrawal of food by mouth, parenteral alimentation which must restore water and electrolytes, correction of acidosis and the administration of dextrose and amino acids. Anemia and hypoproteinemia must be relieved by means of blood and plasma given intravenously. Adequate amounts of vitamin C and B should be supplied hypodermically.

### BLOOD LOSS

The treatment of hemorrhage or loss of blood from any of the various pathologic conditions, such as hemolytic anemia, thrombopenia, hypoprothrombenemia, aplasia and infection, is essentially replacement of this loss by blood transfusion. However, the basic causative factors in these diseases are different and require careful study and differentiation.

The brilliant research in recent years which has established the importance of Rh incompatability in the production of erythroblastosis is too well known to require a review here. My personal experience with this condition has been too limited to add anything of value to the already voluminous and at times confusing literature. It is universally accepted that the infants should receive Rh-negative blood either in the form of multiple transfusions or in massive replacement. Until the indications for this latter procedure are more clearly defined and the technic perfected, it should be attempted only with the greatest caution.

Vitamin K is administered in practically all cases of bleeding encountered during the neonatal period. It is a safe and certainly a harmless procedure, but its value is doubtful. Instances of true hemorrhagic disease of newborn infants are rare, and for them this therapy is specific. However, blood is equally important, and, if there has been considerable hemorrhage which commonly occurs from the gastrointestinal tract, blood should be administered intravenously in amounts adequate to restore the loss.

Congenital thrombopenia may present an emergency in the form of massive hemorrhage from the bowel or extensive subcutaneous hemorrhage. Repeated transfusions over a period of months is sometimes required before recovery is complete.

Congenital hemolytic anemia, though rarely discovered during the neonatal period, may produce profound anemia in the first few weeks of life. Recently I observed an infant requiring splenectomy at 8 weeks of age. Several transfusions were required before operation was attempted.

### ADRENOCORTICAL APLASIA

A rare condition may be observed during the neonatal period; it is characterized by cyanosis, vomiting, evidence of intestinal obstruction, diarrhea alternating with constipation, intractable dehydration, shock, collapse and death.

I have observed 3 male infants in one family exhibiting these symptoms, and in at least 1 the autopsy seems to have clearly proved the diagnosis. These infants were all rather large, exhibited cyanosis at birth or shortly after and began vomiting severely at about 3 weeks of age. They failed to gain from the start and were weaned at 3 to 5 weeks. Pyloric stenosis was suspected in each, and in 1 surgery was resorted to but no definite disease was found. Inability to maintain hydration was striking and suggested the probable diagnosis. Although studies of the chemical content of the blood failed to prove unequivocally the diagnosis of adrenocortical hypofunction, they were suggestive, and 1 infant was kept alive and in good nutrition for seven months by the administration of adrenal cortical extract hypodermically and the addition of large amounts of sodium chloride to the dietary. Attempts were made to reduce the dose of the hormone, but the condition promptly became worse and, although treatment with the original amount of cortin was resumed, the child suddenly went into collapse and died. The autopsy showed decided hypoplasia of the adrenal cortex. A detailed report of these cases will be published at a later date.

### COMMENT

It is obvious that many of the emergencies encountered during the neonatal period may be prevented by improved obstetric care and by closer cooperation between obstetrician, pediatrician and anesthesiologist. For the pediatrician, gentleness and restraint should be exercised in the care of these patients. Overenthusiastic therapy, especially in infants suffering with asphyxia and intracranial injury, should be avoided. The greatest caution must be exercised in all parenteral administration of fluids. The prevention of infection in the nursery by rigid enforcement of all measures which are known to be of value, and the chief of these is the liberal use of soap and water. The early detection and immediate adequate treatment of infection may save the lives of many of these infants.

## ABSTRACT OF DISCUSSION

Dr. Fred L. Adair, Chesterton, Ind.: The more thorough the antenatal care and the more meticulous the attention given during the intranatal period and the immediate postnatal phase the fewer are the emergencies that will arise during neonatal and later infant life. Dr. Roberts stressed the importance of accuracy and gentleness in the neonatal management of infants and pointed out the dangers of indiscriminate and too vigorous therapy. To these ideas, which I heartily endorse, I should like to add the importance of preparedness and promptness in initiating the indicated procedures. There is considerable disability and death of potentially normal fetuses and infants.

---

[8] Frant, S., and Abramson, H.: Epidemic Diarrhea of the Newborn in Brennemann, J.: Practice of Pediatrics, Hagerstown, Md., W. F. Prior Company, Inc., 1945, vol. 1, chap. 28, p. 19.

The major problem is the prevention of these disabilities and deaths. This does not mean, however, that one should ignore the problems arising from developmentally and hereditarily handicapped fetuses and infants. Two factors relative to intrauterine life have an important bearing on the immediate establishment of normal extrauterine life. The first relates to respiration. Dr. Franklin F. Snyder has shown that respiration occurs in the intrauterine fluid medium and that as long as this fluid contains no irritating or inflammatory factors no damage results. It has also been demonstrated that the uterine cavity does not remain sterile during labor and that the amniotic sac acts as a barrier to bacterial invasion of the amniotic fluid. The conclusion is that the artificial rupture of the amniotic sac is not warranted except for strict therapeutic indications related to the proper management of labor largely in the interest of the mother. The second point has to do with the decided environmental changes which occur at the moment of birth with a drop in temperature of about 20 F. or more, evaporation and radiation in an atmospheric medium. There is also the rather abrupt circulatory change, the establishment of atmospheric respiration and the sudden release of pressure from uterine contractions and the structures surrounding the birth canal. These rapid and radical adjustments constitute serious handicaps for premature, traumatized and anoxemic infants. These especially must be ushered into the world with gentleness, warmth and a favorable respiratory environment. The respiratory passages must be cleared immediately. I have usually practiced prompt inversion of the infant, so that fluids may gravitate away from the larynx and are kept away until free respiration is established. A soft rubber ear syringe may be used to suck and blow secretions from the mouth and nares. The tracheal catheter is a valuable adjunct in special cases. The quicker oxygen is delivered to the lungs the better.

Dr. Nina A. Anderson, Cincinnati: The presentation of Dr. Roberts' paper at a joint session of the Section on Obstetrics and Gynecology and the Section on Pediatrics is appropriate, since some of the emergency conditions of the newborn infant may be prevented by good obstetric care and untoward results for others may be averted by early detection and treatment during the neonatal period. Alert and continuous observation is essential as an initial impression of well-being may be wrong, the infant showing alarming signs in the nursery within a few hours after birth. Active therapeutic measures for the newborn infant should be as physiologic as possible, and a trained team to care for the infant immediately after birth is highly recommended. There are certain dangers attendant to mouth to mouth breathing. The method may be used overzealously in an infant who is in poor condition. There is the possibility of transmitting infection. In the treatment of the severely apneic infant, the intratracheal administration of oxygen is becoming more widely accepted. If a resuscitator is used, it should be of the type which delivers oxygen directly into the posterior part of the pharynx, and it is highly recommended that the machine be hand operated, so that when the infant takes a breath the pressure can be discontinued by the operator and started again if thought necessary. The choice of analgesia and anesthesia for the mother should be determined by its recognized minimal effect on the fetus. Although carbon dioxide is not indicated for the immediate treatment of an apneic infant, it does play a role in improving the character of respirations once oxygen saturation is achieved, and used intermittently it is of benefit particularly to the premature infant. Since the incidence of intracranial hemorrhage is so high in Dr. Roberts' series, I would like to ask whether he found any correlation with the size of the premature infant or with any predisposing factor for the premature labor. It is unfortunate that the misunderstanding of the properties of vitamin K is so widespread. Vitamin K can affect hypoprothrombinemia, but it cannot relieve bleeding due to other blood dyscrasias or to trauma. In the doses usually given it can do no harm, and its use for the prevention of hemorrhagic disease of the newborn is justified. In general, the occurrence of infection in a nursery varies inversely with the goodness of technic, but outbreaks may occur in well ordered surroundings.

Dr. M. Hines Roberts, Atlanta, Ga.: In reply to Dr. Anderson's question regarding the weights of premature infants suffering with intracranial damage, I can only repeat that in the study there were 409 deaths of infants weighing 1,000 to 2,500 Gm. Of this number, 117 showed evidence of intracranial damage. The exact number of premature infants in the various weight groups exhibiting this pathologic condition is not immediately available. Subdural hematoma was diagnosed at autopsy in 3 infants of this group. Interest in erythroblastosis has been so intense in recent years that one is prone to give scant consideration to certain other important diseases of the newborn producing great loss of blood. I should like to point out that congenital thrombopenia may produce profound anemia and even death, because of massive hemorrhage, chiefly from the bowel or under the skin. Repeated blood transfusions over a period of weeks or even months may be required before recovery is complete. Congenital hemolytic icterus may present an emergency in the neonatal period. Recently I encountered 2 cases exhibiting the classic picture of this condition during the first few weeks of life. Anemia was profound. Several transfusions were required before surgical treatment could be attempted. Splenectomy was done in each instance at approximately 8 weeks of age.

# UNDECYLENIC ACID GIVEN ORALLY IN PSORIASIS AND NEURODERMATITIS

## A Preliminary Report

HENRY HARRIS PERLMAN, M.D.
Philadelphia

Rothman and his co-workers[1] showed that with the onset of puberty in children the sebaceous glands of the scalp start to secrete a sebum which contains, in higher concentrations than before puberty, saturated fatty acids of a low boiling point with selective fungistatic and fungicidal action on Microsporon audouini. I conceived the idea that the oral administration of one of the saturated or unsaturated fatty acids might be therapeutically effective in the treatment of tinea capitis (M. audouini). I have not found in the literature any reference to the oral administration of a pure saturated or unsaturated fatty acid.

In cases of tinea capitis it was decided to start first with undecylenic acid, because it was most easily obtainable. Toxicity tests were done on rabbits, mice and guinea pigs, and the acid was found relatively nontoxic. The acid was put up in capsules and perles (usually 0.5 Gm. each). Four children, aged 8, 9, 11 and 14 years, respectively, were treated with the acid. Doses averaged 1 Gm. given three times daily. The period of treatment lasted several months. Results were encouraging. Under Wood's light there was less intense fluorescence, fewer fluorescent hairs and also an occasional negative culture. However, there was no ultimate cure. The experiment was discontinued, although it was felt that with increased dosage cures might have been effected.

The most positive effect of treatment with undecylenic acid was the profuse desquamation of the scalp, which suggested to me that undecylenic acid might be effective in the treatment of psoriasis, and on April 29, 1948, I gave the undecylenic acid for the first time to a patient with psoriasis (W. C. R., table). The table shows briefly the essential data pertinent to each case and the results obtained.

---

Dr. Leonard G. Rowntree reviewed the report.

J. H. Wallace Jr., Ph.D., of The Wallace Research Laboratories, Princeton, N. J., supplied all of the undecylenic acid in perles and capsules which was used in this study.

[1] Rothman, S.; Smiljanic, A.; Shapiro, A. L., and Weitkamp, A. W.: Spontaneous Cure of Tinea Capitis in Puberty, J. Invest. Dermat. 8:81-98 (Feb.) 1947.

Exfoliation of the scalp begins promptly after the chemical is administered, usually within a day or two, and the exfoliation continues for many weeks. After several weeks of profuse peeling of the scalp the coarser scales become thinner and less abundant. Scaling continues for some time even after the acid therapy is discontinued, and, while ultimate clearing of the scalp is not seen for many weeks or perhaps months after the treatment is started, evidence of desquamation of the scalp can be seen long after the lesions of the glabrous skin have disappeared. Simultaneously with the exfoliation of the scalp, the disseminated guttate and larger psoriatic lesions seen on the glabrous skin begin to show evidence of improvement. So far there has not been any ironclad rule which determines the order in which the psoriatic lesions disappear or any definite means of foretelling which type of patient will respond more rapidly. Factors to be reckoned are undoubtedly the duration of the psoriasis, the sites involved and the optimum dose, which is far from realization as yet. In some patients, clinical response was not noticed until after three months, when large plaques of psoriasis began to disintegrate and were soon afterward replaced by normal skin. On the other hand, in the subacute and chronic disseminated lesions scattered more or less generally over the entire body, I have been amazed at the rapid therapeutic response after comparatively few weeks of treatment. This has been even more noticeable since the doses have been increased, beginning with 15 capsules, 0.5 Gm. each, of undecylenic acid daily in divided doses (total 7.5 Gm.) rather than the smaller doses which were first used. Again it has been my observation in those cases involving chronic indurated plaques of many years' duration, that an improvement in those plaques will continue for a time and then slow down and even stop. Later, even though the acid therapy has been discontinued, improvement will continue until complete involution in many cases. An interesting feature observed is that, with the continued use of undecylenic acid before and after the skin has cleared up, new lesions fail to appear and in those few instances in which new lesions have appeared they appear to be short lived, disappearing spontaneously. In other words, it would seem that undecylenic acid serves to inhibit the recurrence of psoriasis in some manner which at the present time is not quite clear. Although sufficient time has not elapsed to justify a positive conclusion, I think that it is highly probable that the recurrence of psoriasis can be prevented, at least in a significant proportion of cases, by a maintenance dose of undecylenic acid.

* No itching was present. † Cases reported in detail in paper. ‡ Itching variable.

It is felt that the chronic indurated localized plaques, such as those which appear on the elbows and over the knees, respond less rapidly to treatment than do the disseminated lesions on other parts of the body. In fact, in lesions of this type of psoriasis it appears that undecylenic acid is a slow-acting drug.

One of the earliest symptoms to disappear in treated patients is itching. Relief of itching is sometimes noticed as early as two days after institution of treatment with undecylenic acid. On the other hand, in some instances itching is worse after the start of treatment and may be rather annoying. However, this symptom disappears after treatment is continued and may then be complained of only intermittently until ultimate disappearance of the psoriatic lesions.

At present it seems that the greatest benefit from undecylenic acid in the treatment of psoriasis is in the subacute and chronic lesions which are more or less generalized on the body. In psoriasis of this type of only a few years' duration, remarkable improvement has been noticed even after as short a period as two to three weeks. Exfoliation of the lesions is preceded by a drying of the scales, which at times become friable and break off, leaving a somewhat reddened skin without bleeding points. All of the lesions become paler and less heaped up. Patients complain of a tightening of the skin, which they describe as feeling stretched and taut. Disintegration of the psoriatic lesion occurs either from within outward or from without inward. Peeling which occurs from outside inwardly is often preceded by an areola of redness. At times circinate definitely circumscribed hyperkeratotic plaques clear in the center, leaving a circinate elevated border which surrounds the clear or slightly erythematous skin in the center, not infrequently resembling lesions of ringworm on the glabrous skin. Finally, the slightly elevated border disintegrates and the thin tissue paper-like scale falls off, leaving normal skin. Frequently at the site of scales of prior lesions hyperpigmented skin is left. However, when the skin has been tanned by the summer sun, the skin at the site of the scale seems by contrast to be depigmented. In a short time the sites of the previous scales cannot be distinguished from normal skin.

Frequently improvement in the nails is seen to occur when they are the seat of psoriatic involvement. The heaped up hyperkeratotic material becomes loosened from the distal portion of the nail and disintegrates beneath the nail. The yellowish discoloration of the nail itself becomes transformed into normal pink after comparatively short periods, a few weeks or a month.

## DOSAGE, METHOD OF ADMINISTERING UNDECYLENIC ACID, UNTOWARD EFFECTS AND REACTIONS

An optimum dose has not yet been determined. In the first series of cases doses were comparatively small, but it was noted that with increased dosage better results were obtained. In subsequent patients dosage was increased rapidly. The initial dose for most adults is now 5 perles, each containing 5 Gm. of undecylenic acid, given three times daily after or before meals or in divided doses, with a daily total of 7.5 Gm. This dose is gradually increased to 10 to 15 Gm. daily in divided doses. The effective dose for the average adult patient seems to be 15 or 20 perles (10 Gm.), given three times daily for many weeks, without any harmful effect and without any disturbance of the gastrointestinal tract.

Among the symptoms produced by the ingestion of undecylenic acid are nausea, vomiting, a burning sensation referred to the epigastrium, frequent bowel movements and diarrhea. Many patients complain of a bitter taste in the mouth similar to the taste of gall or a "rotten herring" and which occurs within a few minutes to several hours after ingestion. Another distressing symptom is belching, with a residual taste in the mouth of rancid oil (butyric acid). Probably much of the stomach distress and nausea could be eliminated by the use of enteric coated perles. They are not yet obtainable. The stomach distress and nausea can be prevented and relieved with carbonated waters, soft drinks or ½ teaspoonful of sodium bicarbonate in water, with the perles or a short time after the perles are taken. On occasions when vomiting occurred, the medication was stopped. With resumption of medication the vomiting did not recur. Diarrhea, while it occurred in some of the patients, was of short duration and ceased of its own accord even though medication was not interrupted.

Other symptoms which apparently could be attributed to the ingestion of the drug are folliculitis, localized minute abscesses on the posterior part of the neck, headache, conjunctivitis and axillary adenitis. All these symptoms promptly disappeared with temporary discontinuance of treatment and did not recur when it was resumed. A few patients complained of frequent urination experienced soon after ingestion of the drug. This symptom abated after a few days in 1 patient; in another it persisted for a while. Routine observation of blood pressure, respiratory and heart action, pulse rate and temperature and urinalysis failed to indicate any abnormalities.

I wish to caution against the general use of undecylenic acid until thorough scientific research has been completed. Frequent urinalysis and complete blood cell counts should be done while the drug is being administered, and the physician should be continually alert for any untoward reaction.

## NEURODERMATITIS

Undecylenic acid has been tried in a small number of patients with neurodermatitis, in order to determine the effect of this unsaturated fatty acid on the pruritus complained of and to find out whether the chemical had any therapeutic effect on the lichenified indurated plaques common to this dermatosis. From the small number of patients studied to date, it appears that undecylenic acid has a definite effect on the lesions of neurodermatitis.

## REPORT OF CASES

CASE 1.—Mrs. F. E., aged 37 years, a housewife, was first seen April 13, 1948, because of severe unbearable itching of both upper eyelids of four years' duration. Various topical medicaments and ultraviolet rays had been given by dermatologists but had been ineffective. Erythematous indurated lesions were then on the eyelids, with a thickened leathery feel and scaling; the lesions were more definitely pronounced on both upper lids than on lower lids. Results of various patch tests (including with finger nail polish) were negative as were those of all other laboratory tests. No lesions were present on other parts of the body. Various therapeutic measures were ineffective. On June 13 undecylenic acid in capsules (0.5 Gm.) was given three times a day, and the dose was gradually increased to 1.5 Gm. three times a day by the end of the first week. After a month perles containing the same amount (0.5 Gm.) were used, 2 perles three times daily (total 3 Gm. daily). Itching improved on the second day and had disappeared by the fourth day. Increased peeling of both upper lids commenced on the second day and reached a maximum at the end of the week with coarse scaling, after which time desquamation continued irregularly but with a fine scale. The eyelids appeared and felt softer and velvety, having lost their thick leathery indurated feel. As the patient put it, they felt "lubricated" instead of "tight and heavy." Although erythema and scaliness still continued, there was definitely less than when the patient was first seen. Treatment was continued with regularity (1 Gm. three times daily) with progressive improvement and complete absence of itching until July 25. Treatment with perles was then stopped to determine the effect of discontinuance of therapy. Almost immediately there was a return of itching, milder, however, than the original itching, and both eyelids became erythematous and scaly. The patient insisted that she again be given the perles of undecylenic acid, which were given one week after stoppage, in doses of 1 Gm. three times daily. Itching and erythema promptly subsided, and scaliness diminished. On October 18 the dose was increased to 2.5 Gm. (three times daily), with excellent effect on the residual erythema and scaliness. Because of a developing hyperpigmentation of the upper and lower lids treatment with the perles was discontinued on December 12. There was a return of slight itching and erythema. The hyperpigmentation surrounding the lids has largely faded and the lids did not become thick and indurated. They remained smooth and velvety to the touch. There were no untoward symptoms except a softer stool at the start of the medication.

Case 2.—Mrs. M. B., aged 66, a housewife, was seen on Aug. 30, 1948, with severe itching in the vagina, on the chin and in both antecubital areas. There were several erythematous papular plaques in both antecubital areas, of two years' duration. The patient was very nervous. One perle, containing 0.5 Gm. of undecylenic acid, was given three times daily, with immediate improvement the following day. Medication was continued for one week. There was a recurrence on November 18. Treatment with perles in the same dosage was repeated. There was complete disappearance of the rash and itching after two days. Medication was discontinued, without recurrence.

Case 3.—Mr. S. R., a tailor, aged 53 and married, was first seen July 18, 1948, complaining of itching and rash of twelve years' duration, which had been practically continuous. Examination revealed the typical lichenified indurated erythematous papule-like lesions common to neurodermatitis. Areas involved were the inner aspects of both thighs, entire scrotal area, sacral area, anal cleft, both buttocks and posterior area of the neck. Various forms of topical therapy and roentgen therapy had been used, with only temporary improvement. Undecylenic acid, 0.5 Gm. three times a day, was prescribed. One week later itching was still present, but lesions seemed paler. Treatment continued. Three weeks later there was a decided lessening of the itching. Six weeks later the itching was minimal and the patient stated that he felt better than at any time in the previous twelve years. On November 14 the dose was increased to 2 Gm. (three times daily). On December 20 itching was slight and the lesions decidedly improved.

Case 4.—Mrs. W. B., aged 30, a housewife, was first seen Nov. 18, 1948, complaining of severe itching in the lumbar region. Examination revealed erythematous papular lichenified well demarcated plaques in the lumbar region and abdomen, of eight to nine years' duration. Undecylenic acid was prescribed, 0.5 Gm. three times daily. One week later all lesions had disappeared from the abdomen and lumbar region and there was no itching. The following week several new patches of neurodermatitis were noticed on the lateral aspects of the thighs and smaller similar lesions in the intrascapular area. The dose was increased to 1.5 Gm. three times daily and treatment continued for three weeks. At that time the lesions had completely disappeared and there was no itching.

Case 5.—Mrs. F. D., aged 27, a housewife, was first seen on Nov. 27, 1948, for a rash on the anterior and lateral aspects of the neck of five months' duration. She had received topical therapy from a number of other physicians without improvement. Examination disclosed typical erythematous lichenified papules on the lateral and anterior aspects of the neck, on both upper eyelids and behind each ear. The eyelids showed scaliness, and there was a reddened area on the left lower eyelid. Itching was severe. The patient was extremely nervous and stated that she worried a great deal. Diagnosis of lichen simplex chronicus (Vidal) was made, and undecylenic acid, 2.5 Gm. three times daily, was prescribed. The first four days the patient took only 0.5 Gm. three times a day by mistake. The fifth day the patient began taking the prescribed dose, 2.5 Gm. three times daily. One week later the rash was scarcely noticeable and the itching had completely disappeared. When she was last seen December 23, there was only slight residual erythema and no itching.

Case 6.—Mrs. I. L., aged 60, a housewife, was first seen Nov. 15, 1948, complaining of severe itching of the external genitalia, the vaginal mucosa and the inner aspects of both thighs of several years' duration. Examination revealed erythematous plaques on the external genitalia, with lichenified patches on both buttocks and the sacral region. Crural areas of both thighs was also definitely lichenified and erythematous, as was also the lower third of the anterior aspect of the thighs. Undecylenic acid, 1 Gm. three times daily, was prescribed. Two weeks later the erythema was practically gone, the lesions were greatly improved and the itching was minimal; in fact, the patient was able to sleep through the night without scratching. The same dosage was continued.

Case 7.—T. R., a female student aged 17 years, was first seen Oct. 28, 1948. As an infant she had been treated by me for atopic dermatitis. Her father suffered from hay fever. Examination showed a dry scaly eczematized skin on both cheeks and the forehead. Similar lesions were on the anterior region of the neck and behind the ear lobes, and there was lichenification and scaling of the fingers of both hands. The antecubital regions and popliteal areas were the seats of the typical lichenified erythematous plaques commonly seen in atopic dermatitis. There was severe itching. Undecylenic acid, 0.5 Gm. three times a day, was prescribed and a mixture of pine tar ointment and zinc oxide paste in equal amounts was ordered for topical application at bedtime. By November 4 the itching had diminished and there was a noticeable improvement in the scaliness and dryness of the lesions. By November 11 the itching had completely subsided and the lesions, though definitely clinically improved, were still very dry. Undecylenic acid and topical applications were discontinued about November 20. The patient was last seen December 23. All lesions had disappeared with the exception of a circinate area of erythematous scaly plaques on the dorsal surface of the right wrist.

Case 8.—J. D. R., an Italian engineer aged 65, had had asthma for ten years. In 1947 he noticed a rash on the left leg which spread over the entire body. He was treated topically and with antihistaminic drugs by various physicians. He was first seen May 10, 1948. There was a generalized exfoliative dermatitis on the entire body with severe itching and redness. The skin was acutely inflamed with weeping, crusting and exfoliation. Itching at times was unbearable. Undecylenic acid, 1 Gm. three times a day, was prescribed, with topical applications of a mixture of equal parts of olive oil and lime water. Itching was improved after two weeks. The skin showed little improvement after four weeks. On July 19 the skin showed the first evidence of improvement, exfoliation had subsided and normal areas of skin were seen on the forearms and lower extremities as well as on the body. When the patient was last seen, December 27, itching had completely disappeared and the skin was smooth and clear except for a few small circinate eczematized plaques on the upper and lower extremities. The treatment with undecylenic acid perles and topical applications was continued.

## THERAPEUTIC INDICATIONS

Until carefully controlled scientific investigations have been carried out, one can only speculate how undecylenic acid produces its therapeutic effect on the skin in psoriasis, neurodermatitis and the arthropathies. Psoriasis may be due to a metabolic disturbance, but this, too, is purely speculative and cannot be determined until chemical investigation and metabolic studies have been carried out in large numbers of patients.

## SUMMARY

A series of 17 patients with chronic psoriasis, both localized and generalized, were given gradually increased doses of undecylenic acid by mouth for varying periods of time, with definite improvement in the psoriasis characterized by a disappearance of the psoriatic lesions, a permanent relief of the itching complained of and, in several instances, associated with arthropathies, a definite disappearance or improvement in the joint pains. A series of 8 patients with neurodermatitis were treated with undecylenic acid by mouth for varying periods of time, with improvement or disappearance of the lesions and itching.

Definite claims for undecylenic acid cannot be made from the comparatively small number of patients studied at this time. However, undecylenic acid seems to hold a great deal of promise in the improvement and possible prevention of recurrences of psoriasis and neurodermatitis. Time alone will tell the story of this remarkable unsaturated fatty acid in the treatment not only of these diseases but of many unrelated disturbances. This preliminary report is made to spur research, clinical and scientific, on undecylenic and the other unsaturated fatty acids, in all phases.

1726 Pine Street.

# REACTIONS TO PERTUSSIS VACCINE

JOHN A. TOOMEY, M.D.
Cleveland

The report of Byers and Moll[1] on irreversible reactions following the injection of pertussis vaccine was disturbing, since prior to it this antigen had been considered innocuous. Their observations cover a ten year period and are summarized in table 1.

In case 2, 1 of 2 siblings had epilepsy and an uncle had hydrocephalus; in case 9, 1 of 2 siblings had hydrocephalus, and in case 12, 1 patient had febrile convulsions. No cases appeared between 1940 and 1942; 1 to 4 cases were seen during each of the other years. Twelve patients had received fluid toxoid. Five had reactions after the first, 4 after the second and 6 after the third dose. Two died and 8 had irreversible cerebral damage. The dose for 4 patients was unknown. Six of the remaining 12 had been given from 40 to 45 billion, 3 had 30 billion and 2 had 10 billion bacteria, after which reactions occurred. Recently Dr. Byers informed me of 4 additional cases.

TABLE 1.—*Observations of Byers and Moll on Encephalopathies Following Administration of Pertussis Vaccine*

| Case No. | Age, Mo. | Manufacturer | No. of Bacteria, in Billions/Dose | Dose No. | Results |
|---|---|---|---|---|---|
| 1 | 15 | ? | .. | 3 | Improved |
| 2 | 18 | A | 30 | 2 | *Familial epilepsy; poor* |
| 3 | 12 | B | 40 | 2 | Poor |
| 4 | 7½ | C | 40 | 3 | Apparently better; improved slightly |
| 5 | 18 | E | 40 | 1 | Exposure to whooping cough; improved |
| 6 | 7 | E | 30 | 2 | Poor |
| 7 | 11 | F | 40 | 3 | Poor |
| 8 | 10 | F | 30 | 1 | Died; respiratory infection (Pneumococcus) |
| 9 | 6 | F | 45 | 3 | Died; 1 sibling with hydrocephalus |
| 10 | 9 | ? | 10 | 1 | Poor |
| 11 | 5 | ? | ? | 1 | Poor |
| 12 | 7½ | F | 40 | 3 | Poor |
| 13 | 6 | E or F | ? | 2 | Improved |
| 14 | 6 | G | 10 | 1 | Slight convulsions |
|  |  |  | 10 | 2 | Slight convulsions |
| 15 | 8 | A and B | ? | 3 | Otitis; better (vaccinated simultaneously |

I sent a questionnaire to (1) all the local pediatricians in northern Ohio; (2) all those who had written on the subject of whooping cough, and (3) the members of the profession in general through the pages of *Quarterly Review of Pediatrics* and the *American Journal of Diseases of Children* for specific information on this subject. The data received are summarized in table 2.

I decided to try to obtain an answer to a simple question, "Did the patients have convulsions after vaccination?" There may be a misunderstanding as to what constitutes an encephalopathy, but everyone can recognize a convulsion.

The following physicians were consulted and reported no convulsions after injections: William Sako, New Orleans; John Bigler, Highland Park, Ill.; W. W. Waddell, Charlottesville, Va.; Jean V. Cooke, St. Louis; John R. Wilkey, Seattle; Paul Hamilton, San Marino, Calif.; Louis Sauer, Evanston, Ill.; V. K. Volk, Saginaw, Mich.; H. J. Parish, Beckenham, Kent, England; Leila Daughtry-Denmark, Atlanta, Ga.; Herman Gold, Chester, Pa., and J. W. Epstein, Fred Rittinger, Henry F. Saunders, Otto L. Goehle, Chauncey Wyckoff, Isadore Silber, Clarence Weidenthal, Alexander N. Freed, William M. Champion, Arthur J. Horesh, Oscar B. Markey, Charles F. McKhann, Paul C. Crone, Joyce I. Hartman, R. W. Fullerton, Joseph E. McClelland, Melvin F. Yeip, Walter Heymann, Charles L. Ruggles, Paul G. Albrecht, Robert B. Hauver, Hugh J. Leslie and Warren C. Fargo, Cleveland.

Dr. J. W. Epstein gave injections to more than 7,000 patients; Dr. Chauncey Wyckoff gave injections to more than a thousand children; Dr. Daughtry-Denmark has used vaccine since 1933. None of these physicians has seen convulsions following the inoculation of pertussis vaccine.

There were at least 38 well authenticated cases. Data were given in 25 of these. The facts were incomplete for 1 child, but of the remaining 25, 23 recovered completely, 2 had bad reactions and died, 4 had subsequent convulsions, 4 were simultaneously ill with other diseases and 5 had convulsions previous to injection. This leaves the 12 reported by Buchanan, on which I have only the general statement: "All showed irreversible changes."

I could find no common denominator. In the cases of Byers and Moll, it seemed fluid toxoid was given oftenest. There seems a disproportionate number of cases reported in the East and Midwest. This could easily be explained on the basis of incomplete reporting from other parts of the country.

Of all the patients seen in Cleveland and vicinity, none had irreversible changes.

Faber stated that these reactions may be due to: (1) constitutional reactions occurring in the patients themselves; (2) immediate intravenous injection of vaccine; (3) antigen antibody responses to previous specific sensitization; (4) process of pyrogens in bacterial organisms, and (5) damage of cerebral vessels from toxins in pertussis.

Only 5 patients in this series could have been constitutionally predisposed. One can agree with Faber that intravenous injection may cause reactions. This cause is unlikely, but, as he recommended, it should be taken into consideration.

That reactions were due to antigen antibody response could be rejected, since the children were not previously immunized. Some were children who had been given first injections. The process of immunizing mothers has been so recent that one could ignore this as a possibility.

It is true that this antigen might give pyrogen reactions. Temperatures were high both in the series of Byers and Moll and in that herein reported on. Perhaps the identification of pyrogens might be possible.

Hemophilus pertussis does produce a toxin, and many persons during the course of the disease have had encephalopathies. Whether the reaction may be due to fever or a toxin has to be determined.

---

From the Department of Pediatrics, Western Reserve University, and the Department of Contagious Diseases, City Hospital.

Read before the Section on Pediatrics at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 23, 1948.

[1] Byers, R. K., and Moll, [illegible] Following Prophylactic Pertussis Vaccine, Pe[illegible] 1948.

In many instances, children were given injections of vaccine grown on human blood. This human blood may have been carried into the vaccine, together with many questionable antigenic factors.

I think, with Faber, that the National Institute of Health should test all whooping cough vaccine for pyrogens.

### SUMMARY

1. No child should receive injections of pertussis vaccine in large amounts (40 billion organisms, double strength) who has (*a*) any family history of convulsions, (*b*) a present history of convulsions or (*c*) illnes of any kind, especially if it pertains in any way to the central nervous system.

2. If there is any doubt, the dosage should be decreased.

3. A report should be made of every apparent reaction, and complete data should be kept by the physician.

4. Perhaps the United States Public Health Service should standardize vaccine not only for potency, but for aging.

5. There are not enough reported aftermath reactions to discontinue the use of vaccine.

Table 2.—*Summary of Data Received in Answer to Questionnaire on Incidence of Reaction to Pertussis Vaccine*

| Name of Physician | Cases Counted | Total No. Cases | Manufacturer | Dose No. | Clinical Reactions |
|---|---|---|---|---|---|
| Joseph H. Lapin, New York.......... | 1 | 1 | Sharpe & Dohme, Inc. | ? | Convulsions; better |
| | 2 | 1 | Sharpe & Dohme, Inc. | ? | Convulsions; better |

| Theodore P. Herrick, Cleveland...... | 31 | 1 | Parke, Davis & Co. | 3 | Had otitis media at time; convulsions; recovered |
| | 32 | 1 | Parke, Davis & Co. | ? | Had tonsillitis at time; convulsions; recovered |
| John H. Davis, Cleveland............ | 33 | 1 | ? | ? | Convulsions; previous neurologic reactions and birth injury; better |
| | 34 | 1 | ? | ? | Mild reaction; better |
| Franklin A. Benes, Cleveland......... | 35 | 1 | Parke, Davis & Co. | 2 | Previous and subsequent convulsions; 2 subsequent injections with no trouble; better |
| Clayton T. J. Dodge, East Cleveland, Ohio | 36 | 1 | ? | ? | Convulsions and high fever; pyelocystitis at same time. (This physician reports 2,715 injections with no complications.) |
| Beulah Wells, Cleveland............ | 37 | 1 | ? | ? | Convulsions after each of 2 injections; previous neurologic reactions |
| Wm. H. Gronemeyer, Midland, Mich. | 38 | 1 | E. R. Squibb & Sons (alum-precipitated diphtheria toxoid) | 2 | Convulsions; good condition afterward |

### ABSTRACT OF DISCUSSION

**Dr. Archibald L. Hoyne**, Chicago: Even though the number of fatal or serious reactions reported from injections of pertussis vaccine appears small, Dr. Toomey's paper is of great importance. Attention is focused on unusual possibilities which may result from the immunization of an infant or child against whooping cough; emphasis is also placed on the state of health, and equally important is the past history of illness and any neurologic data pertaining to the parents or other members of the family. As early as 1937, I believe, Madsen referred to 2 deaths in newborn infants following a second injection of pertussis vaccine. Both fatalities were sudden and unexplained. If the initial reaction is severe, it should serve as a danger signal and no additional injections ought to be given. Brody reported in 1947 the case of an infant who was inoculated with pertussis vaccine a month or two after complete recovery from an encephalitic type of infection. After the first dose of vaccine, encephalitis recurred with flaccid paralysis, with complete recovery. With the second injection there was a repetition of the same symptoms, and the condition persisted for months. Later, a small dose of diluted vaccine was administered intradermally and this was followed by death in a few days. I do not believe that the size of the dose is an important factor. Possibly, the untoward results are due to activation by the pertussis vaccine of some virus harbored by the patient. However, convulsions or encephalitis may be occasioned by any acute infectious disease. Therefore, it seems plausible that pertussis toxin in the vaccine could be accountable. But if that were the causative agent most likely a far greater number of bad reactions would be recorded. Sometimes it is recommended that following the administration of vaccine the site of injection should be massaged. The purpose advanced for doing this is to lessen the likelihood of seepage. However, in my opinion, the procedure is not without danger, for it may promote the entry of vaccine into a blood vessel. If the needle enters the skin diagonally, and not perpendicularly, seepage is not apt to occur, provided gentle pressure is applied immediately after the needle is withdrawn. Practically, the constitutional factor is likely to receive special attention, and unfavorable reactions will probably be attributed by many to some phase of anaphylaxis until there is a better understanding of the actual cause. Improved methods of refinement in the production of pertussis vaccine may eventually eliminate the hazards that have been described.

Dr. Louis W. Sauer, Evanston, Ill.: In isolated cases a customary prophylactic dose of pertussis vaccine (usually fluid) seems to elicit a chain of untoward central nervous system reactions—fever, convulsions and, in some instances, irreversible pathologic changes in the brain. These cardinal findings resemble those occasionally encountered in cases of severe whooping cough. During the ten years of their study, Byers and Moll observed that twice as many children were admitted with pertussis encephalopathy as were admitted with symptoms due to pertussis vaccine. This triad, however, has been reported also after successful smallpox vaccination and after prophylactic doses of diphtheria toxoid, typhoid vaccine and Hemophilus influenzae vaccine. In Dr. Toomey's series the pertussis antigens were made by seven commercial laboratories, and in the Byers-Moll group, by at least eight laboratories. Several of the infants had convulsions after two successive doses. In several, the second convulsion-eliciting dose was made by a laboratory other than that which made the first. In neither series did any 2 children show these untoward symptoms after doses taken from the same vial. It is of the utmost importance in the defense of pertussis vaccine that the remainder of the vaccine in these vials when administered to other infants caused neither convulsions nor pathologic changes in the central nervous system. Alum-precipitated pertussis vaccine and multiple antigens were used infrequently; in only one instance was a booster dose involved. Of far greater significance seems to be the similarity in many of the family histories in both the Toomey and the Byers-Moll series—a high incidence of central nervous system instability (close relatives with epilepsy and siblings with histories of convulsions). This constitutional background apparently is an integral component. Because administration of pertussis vaccine has become in recent years the initial immunization procedure, it has become a factor which precipitates high fever, convulsions and encephalopathy in infants with potentially unstable central nervous systems. The trigger effect of any fever-producing antigen may cause the chain of symptoms. Most of us have encountered an occasional child who repeatedly shows convulsions at the onset of such febrile diseases as acute tonsillitis, otitis media and pyelitis. Had prophylactic doses of a high fever-producing antigen been injected into such a child in infancy, might not convulsions have developed? Byers and Moll resorted to pneumoencephalograms. In 1 patient (case 6), one month after the incriminating dose of antigen, at the age of 8 months, they found "enormous dilatation of the ventricular system." The logical question is: Did such an extensive pathologic lesion of the central nervous system antedate the vaccine, or was it the result of the vaccine? I propose that the chair appoint a committee to study the subject of convulsions and encephalopathy following the administration of any type of antigen—a report to be submitted to the Section on Pediatrics at some future annual meeting.

Dr. John A. Toomey: I agree with Dr. Hoyne that the state of health of the individual patient is important. The physician should not give an injection to a child when it has had any illness, especially otitis media. He should not give an injection to any child who has a neurologic reaction or a history of neurologic reactions or, as one of the speakers mentioned, a trigger type brain mechanism. I agree with Dr. Hoyne that there is a possibility that some virus may be activated by injection of an antigen. This is the standard explanation of what happens in encephalitis following vaccination. There may be a great number of patients who have had reactions, but they have not been reported as yet. Of course, as Dr. Hoyne said, if the vaccine is injected into a blood vessel, an immediate reaction may result. As far as influenza vaccine is concerned, I agree with Dr. Sauer. There is no sense in giving children influenza vaccine. It has not been proved effective. I agree with Dr. Sauer that if a child has any central nervous system involvement, one ought to stop, look and listen before doing the vaccination. I do not quite agree with Dr. Sauer on the number of organisms injected. I think 40 billion is more than enough. Dr. Sauer's experience with his vaccine is good. He uses vaccine that has been grown on human blood. This does not imply, however, that blood materials may not be absorbed in the antigen preparation. There may be a reaction in this. Certainly, such a thing can occur in hepatitis.

# Clinical Notes, Suggestions and New Instruments

## AUREOMYCIN THERAPY OF RECRUDESCENT EPIDEMIC TYPHUS (BRILL'S DISEASE)

EMANUEL B. SCHOENBACH, M.D.
Baltimore

The nonepidemic occurrence of typhus among residents of New York City was first reported by Brill in 1898.[1] A singular selection of persons who had been born in Eastern Europe was described. Later investigations conducted by Maxcy in the Southeastern United States of what was believed to be Brill's disease revealed that endemic typhus in this country was caused by a murine strain of Rickettsia transmitted by the rat flea and was not the louse-borne epidemic type.[2] In 1933 and 1934, Zinsser, through careful epidemiologic analysis of data assembled in New York and laboratory studies on cases observed in Boston, postulated that Brill's disease was probably a recrudescence of epidemic louse-borne typhus and not the endemic flea-borne type observed in Southeastern United States[3] The strains isolated by Zinsser from 3 patients behaved like the European type and supported the belief that Brill's disease represented the classic European infection.[4] Subsequent serologic study of serums obtained from patients ill with Brill's disease in Boston and New York with washed rickettsial antigens have confirmed Zinsser's thesis.[5] This type of infection is of epidemiologic importance because if persons suffering from a recrudescence of epidemic typhus harbor lice, they may become infected and thus initiate secondary dissemination.

To the present, no chemotherapeutic agent has been of value in this disease. Aureomycin, an antibiotic derived from Streptomyces aureofaciens, has been shown to possess decided chemotherapeutic activity in experimental infections with murine and epidemic strains of typhus rickettsiae as well as the rickettsiae of Q fever, Rocky Mountain spotted fever and rickettsialpox.[6] Q fever and Rocky Mountain spotted fever, Eastern type, have been treated with this antibiotic with rapid defervescence and clinical improvement.[7]

A patient, in Baltimore, ill with recrudescent epidemic typhus (Brill's disease), was treated with aureomycin. The clinical response observed in this patient paralleled the experience observed with Rocky Mountain spotted fever, and the therapy definitely exerted a beneficial influence on the course of the disease.

### REPORT OF A CASE

A. H. was a 42 year old Rumanian-born white man, who was first admitted to the Sinai Hospital, Baltimore, under the care of Dr. Milton Sherry on July 20, 1948, for the removal of a thyroid adenoma. An operation was performed by Dr. Alfred Ullman on July 21, and a colloid adenoma measuring 5 by 2.8 by 3 cm. was removed. Postoperatively no unusual complications were noted, and the patient was discharged on July 26. He had received penicillin, 50,000 units intramuscularly every three hours preoperatively and postoperatively to avoid infection and "seconal sodium" (sodium 5-ethyl-5-[1-methylbutyl barbiturate]) and methadone for sedation and analgesia.

The patient convalesced at home and improved progressively until five days before his second admission, on Aug. 5, 1948, when he suddenly experienced a shaking chill, severe generalized headache and pain in the calves of both legs. Acetylsalicylic acid was taken, with only slight relief of the headache and transitory reduction of the fever. His symptoms became progressively worse, and on the evening of the fourth day, at which time a maculopapular rash on the abdomen was noted, a physician administered 200,000 units of penicillin G intramuscularly. Later that evening, the rash became more extensive, the temperature rose to 105 F. and the patient was referred to the Sinai Hospital. No cough or chest pain had been experienced during this illness, but there had been decided anorexia with vomiting on one occasion.

The patient was born in Russia and had suffered from "fleck typhus" in 1918 during an epidemic. He had been in the United States and a resident of Baltimore since 1925. He could remember no insect bites preceding his present illness, and no obvious rat infestation had been observed at his home. He was the manager of a large retail self-service market and had not been at work for at least twelve days preceding the onset of his illness.

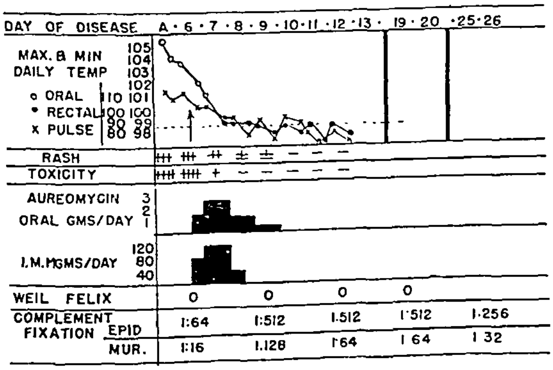

Chart of data in the case reported (Brill's disease in a 42 year old man).

Physical examination on admission showed an extremely ill delirious man complaining of an intense generalized headache. He was lethargic with episodes of anxiety and motor excitement attributed to the headache. The temperature was 105.2 F. (oral); the pulse rate was 112, and respirations were 24 per minute. The blood pressure was 110 mm. systolic and 60 mm. mercury diastolic. The eyes were glazed, and the conjunctivas were congested and diffusely injected with pronounced venous engorgement. A scar over the thyroid area of the neck was well healed, with no evidence of induration. Examination of the heart and lungs revealed no evident abnormality. The abdomen was somewhat distended. The spleen was palpable 2 fingerbreadths below the left costal border. No other visceral abnormalities, masses or hernias were present. On the abdomen, lower part of the chest, back, arms and lower extremities, a salmon-colored discrete maculopapular rash was present. This eruption faded somewhat on pressure. It was not hemorrhagic or petechial. Neurologic examination showed the patient to be lethargic, with slow response consistent with his toxic appearance. Reflexes were depressed, and a Babinski sign was elicited on the left. No confirmatory evidence for pyramidal tract involvement was obtained.

*Results of Tests with Epidemic and Endemic Strains of Rickettsiae*

| Date (August) | Epidemic Strains | Endemic Strains |
|---|---|---|
| 6 | 1:64 | 1:16 |
| 9 | 1:512 | 1:128 |
| 12 | 1:512 | 1:64 |
| 19 | 1:512 | 1:64 |
| 26 | 1:256 | 1:32 |

Laboratory studies showed the urine to be normal. The hemoglobin on admission was 12.9 Gm. (89 per cent), and the white blood cell count was 7,000, with 68 per cent neutrophils, 24 per cent lymphocytes and 8 per cent monocytes. Chemical examination of the blood showed the urea and glucose content to be normal. No parasites or occult blood were demonstrated in the stool specimens. Stool, nasopharyngeal and throat cultures revealed none of the common pathogenic organisms. Blood culture was sterile. The reactions to serologic tests for syphilis were negative. Results of repeated serologic studies with typhoid H and O, paratyphoid A, Proteus $OX_2$ and $OX_{19}$, Brucella and sheep erythrocytes as antigens on August 6, 10, 13 and 19 were all negative. Complement fixation tests, performed by Dr. Herald Cox of the Lederle Laboratories Division, American Cyanamid Company, showed the typical serologic pattern of Brill's disease. The results obtained employing washed epidemic and murine strains of rickettsiae were positive (4 plus) on serial serum specimens, as shown in the table.

Aureomycin therapy was initiated at 12 noon August 6, when the patient's temperature was 103.6 F. (oral). The dose employed was 200 mg. (orally) every hour for three doses initially and thereafter 200 mg. every two hours day and night. In addition, because the patient appeared severely ill, intramuscular administration of 40.0 mg. of aureomycin dissolved in 2.0 cc. of 1 per cent procaine hydrochloride in distilled water was administered three times each day. The dosage of drug employed and the clinical course of this patient are graphically outlined in the figure.

Prompt improvement was noted in the well-being of the patient, with diminution of the headache within twelve hours after aureomycin therapy was started. The next afternoon the temperature was 99.8 F. (rectal). The dosage of aureomycin was reduced to 100 mg. every two hours, and treatment was discontinued at 8 a. m. on August 10. The intramuscular supplement of aureomycin was discontinued on the morning of August 8. Symptomatic improvement with disappearance of the rash paralleled the remission of fever. The patient improved

H.: Pharmacological and Clinical Studies with Aureomycin: A Preliminary Report; Lennette, E. H.; Meiklejohn, G., and Thelen, H. M.: Treatment of Q Fever in Man with Aureomycin.

rapidly and was asymptomatic when discharged from the hospital on August 12. When seen six days later, he was feeling well and was able to perform his duties as manager of a large supermarket during the ensuing week.

This patient was treated on the sixth day of his illness, with subsidence of fever by crisis within twenty-four hours. The rash also diminished rapidly and had disappeared at the end of forty-eight hours except for brownish stains on the abdomen. He received a total of 6.6 Gm. of aureomycin orally during the ninety-two hours of treatment and 240.0 mg. intramuscularly for a forty-four hour period.

### COMMENT

The diagnosis of Brill's disease was made because of the typhoidal appearance of the patient, congestion of the conjunctivas, severe headache, typical eruption and history of previous residence in an endemic typhus zone. Despite his absence from this region of Southeastern Europe for twenty-three years, and the interval since his purported attack of typhus in 1918, recrudescent typhus was considered as the most probable diagnosis. Serologic confirmation was subsequently obtained by complement fixation tests with the specific rickettsial antigens. I have noted the absence of agglutinins for strains of Proteus $OX_{19}$ and $OX_2$ on several occasions when the result of the more specific complement fixation test has been positive. The Weil-Felix reaction, of inestimable aid in diagnosis, cannot be employed to exclude rickettsial infection. The antigen common to strains of Proteus ($OX_{19}$ and $OX_2$) and rickettsiae comprises only one fraction of the antigenic mosaic of either organism.

The course of the disease appeared to be definitely influenced by aureomycin therapy. Among 18 patients personally observed during the past ten years in New York and Boston, febrile lysis occurred on the tenth to sixteenth day of illness. This patient was treated on the sixth day of his illness and was afebrile twenty-four hours later. Although the mortality rate for Brill's disease is almost negligible, it is a severely incapacitating disease and any agent which will materially alleviate the symptoms and shorten its duration is of value. No evidence of any toxicity due to the medication was observed. The intramuscular injections were well tolerated in this concentration for the short period this route of administration was employed.

### SUMMARY

A 42 year old Rumanian born man, ill with recrudescent epidemic typhus (Brill's disease), was treated on the sixth day of disease with aureomycin by oral and intramuscular routes. Prompt clinical improvement was observed. This is the first case of Brill's disease with a serologic pattern consistent with recrudescent epidemic typhus to be reported in Baltimore.

---

**A New Sign of Coarctation of the Aorta.**—By making the patient stoop or bend forward with the arms hanging by the side, collateral arteries under the skin of the back and sides of the thorax suddenly appeared where none were visible before. . . . The reason for the sudden appearance of these arteries with this change of posture was rather puzzling at first. After discussion with Professor Whillis of the Anatomy Department, Guy's Hospital, he suggested that these particular movements simply widened the costoclavicular space. It follows that in cases of coarctation where this sign is positive, there must in ordinary positions be a sufficiently narrow space between the clavicle and the first rib to produce some constriction and obstruction of the subclavian artery. Any movement that increases the costoclavicular space will then relieve this partial obstruction of the subclavian, and so the vessels having their origin from the partially constricted artery will suddenly fill up and become larger so that collateral branches previously invisible will become easily seen. In cases (of coarctation of the aorta) that do not show this sign the space between the clavicle and the first rib is wide enough not to compress even the dilated subclavian artery. We do not think that compression by the other structures in the costoclavicular space, such as the nerve plexus or the scalenus muscles, plays any important part.—Maurice Campbell and S. Suzman, Coarctation of the Aorta, *British Heart Journal*, July 1947.

## REPORT TO THE COUNCIL

*The Council has authorized publication of the following report.*

Austin Smith, M.D., *Secretary.*

## CLINICAL EVALUATION OF ISOPROPYLEPINEPHRINE IN MANAGEMENT OF BRONCHIAL ASTHMA

LESLIE N. GAY, M.D.
and
JAMES W. LONG, M.D.
Baltimore

Within the past two years several reports have appeared covering the use of a new sympathomimetic amine in the symptomatic management of bronchial asthma.[1] This isopropyl modification of epinephrine, racemic 1 - (3 - 4 - dihydroxyphenyl)-2-isopropylaminoethanol, has been named variously "I.P.A." (Specific Pharmaceuticals, Inc.), "Aleudrin" in European literature, and "aludrine" in this country, "isorenin," now "isonorin" (Carroll Dunham Smith), and "isuprel" (Winthrop-Stearns, Inc.). The sulfate salt (aludrine sulfate) was the drug employed in the studies reported here. A purely clinical approach was used to evaluate the therapeutic effects of the drug and to assign it its proper place in the management of bronchial asthma. Four routes of administration were studied and an attempt made to determine the optimum dosage for each. The subjective and objective therapeutic effects of each method will be discussed separately. The patients treated in this series were selected from outpatient dispensary service, emergency room service, private practice and hospital ward groups, and consisted of males and females, of both white and colored races, ranging in age from 15 to 75 years. No attempt was made to classify or separate the asthmatic patients on the basis of allergenic causation. Wherever possible and practical, placebos were employed and their effects compared with those produced by the authentic drug. Patients benefited by placebos were not included in the series.

### SUBLINGUAL ADMINISTRATION

Readily soluble tablets containing 10 mg. of aludrine sulfate were employed as sublinguets. The patient was instructed to place one tablet beneath the tongue the moment that he was aware of an attack coming on, and to allow it to dissolve there without swallowing. If no benefit or ill effect was apparent in fifteen minutes a second sublinguet was to be used, and, after another interval of fifteen minutes, a third tablet could be tried. Repeated trials were carried out by 47 patients, each patient being given aludrine sulfate for the first two weeks, a placebo made to look and taste like the authen-

tic tablet for use the second two weeks and again the original aludrine tablet thereafter. Those patients experiencing mild attacks of asthma reported moderate to marked relief in every instance but one. Only 1 patient in 25 with mild asthma failed to obtain relief using the sublinguet as instructed. The majority (21 out of 25) could completely abort the attack with the use of one sublinguet if taken promptly at the onset of wheezing. If, however, the patient allowed his asthma to increase in severity and become fully established, relief afforded by the linguet taken then was proportionately less and other treatment had to be used. These patients suffering from attacks of moderate severity reported less favorably, only 7 out of 16 obtaining moderate to marked relief, 3 mild relief and 6 of the 16 no benefit at all. Six patients experiencing frequent paroxysms of severe asthma obtained no relief with repeated use of sublinguets. In those patients benefited, relief was generally felt in three to five minutes and lasted from one to four hours. In many instances of mild asthma the patient would report complete relief with one or two sublinguets and no return of asthma for twenty-four or more hours. About one third of all patients using the sublinguets (16 of 47) reported palpitation of a mild fleeting nature, in no instance distressing enough to withhold the drug. Of the 47 patients using this route 2 complained of precordial pain, 3 of headache, 2 of nausea and 1 of nervousness. When all patients were asked to state their preference between the aludrine linguet and the common antiasthmatic tablet combining aminophylline, phenobarbital and ephedrine (which was used routinely prior to the aludrine study), they chose the later combination in a ratio of 3 to 1. The reasons most often given for this choice was the ability of the aminophylline-phenobarbital-ephedrine combination to relieve asthma of severity not appreciably benefited by the aludrine linguet, the greater duration of relief and the relative absence of unpleasant side effects attending the use of the aminophylline-phenobarbital-ephedrine tablets. All agreed, however, that the linguet afforded the quickest relief and that its greatest usefulness was in the prompt abortion of asthma of mild degree.

### ORAL ADMINISTRATION

This was the first route studied and the information gained here as to effective dose, patient tolerance and side effects served as a guide in the approach to other methods of administration. Aludrine sulfate was given in capsule form in doses of 15 mg. to 50 mg. It was found rather early that there is wide variation in both therapeutic response and incidence of side actions among patients. One boy of 15 years experienced such palpitation and dizziness after an oral dose of only 15 mg. that he was able to identify the drug given by inhalation at a later date on the basis of the side effects which resulted. In spite of his apparent sensitivity, however, he obtained no relief of his asthma with this dosage. On the other hand, a woman of 36 years reported that any thing less than 50 mg. of aludrine per dose failed to help her asthma significantly and that the side effects of mild palpitation and nervousness were not objectionable enough to her to preclude use of the drug.

With doses by mouth of 25 mg. or more the majority (80 per cent of 30 patients) experienced side actions of a severe and disagreeable nature sufficient to render the routine use of the drug in such dosage impractical. Of the patients in this group experiencing mild asthma 75 per cent reported moderate to marked relief with doses of either 25 mg. or 50 mg. The larger dose produced side effects of greater intensity and duration without significant increase in the degree of relief afforded. Of the patients experiencing paroxysms of severe asthma only 25 per cent reported significant benefit with doses of either 25 or 50 mg.

As a result of these observations 15 mg. was adopted as the initial trial dose to be given routinely. In spite of this smaller dose 75 per cent of 36 patients receiving it reported some side effect. With this dosage however, the side actions were of a mild and fleeting nature and in only 1 instance (already reported) of a severity great enough to prohibit use of the drug. The nature and incidence of these side effects will be discussed separately. Eighty-three per cent of all patients with mild asthma reported moderate to marked relief following 15 mg. of aludrine taken at the onset of the attack. Those patients who allowed their asthma to go unabated and those experiencing severe asthma rapidly after onset failed to obtain significant benefit from 15 mg. of aludrine and had to resort to epinephrine by inhalation or injection, aminophylline, oxygen, etc.

Seven patients with chronic or frequently recurring low grade asthma (subacute status) were given 15 mg. doses at 8, 12, 4 and 8 o'clock in attempt to allay or reduce the frequency of attacks, but no appreciable results were observed. While there was a tendency to a lessening of the severity of the wheezing in some instances, none of the patients was freed of his asthma without recourse to supplemental forms of treatment.

Those patients helped by oral medication reported relief in twenty to thirty minutes with durations ranging from one to four hours. As with the linguets, many mild attacks aborted early completely subsided for twenty-four or more hours.

### ADMINISTRATION BY INHALATION

Aludrine sulfate in an isotonic solution of 1:200 strength was administered by hand nebulizers to 48 patients. This group included patients treated in the outpatient clinic, on the hospital ward, in the emergency room and those furnished with solution and nebulizers for use at home. Patients were instructed to take five inhalations at the very onset of wheezing and to repeat this again in five minutes if necessary and if no untoward symptoms appeared. After several trials each patient was able to determine for himself the optimum number of inhalations and courses to use in his individual case. As one would expect, dosage had to be individualized, the milder asthma requiring but a single course of three to five inhalations while the asthma of greater severity called for repeated courses of six to eight inhalations. Of the four routes of administration, we believe the inhalation of a nebulized spray produced the most beneficial therapeutic response and the lowest incidence of untoward side actions. Every patient experiencing mild asthma reported immediate and complete relief after one course of 3 to 6 inhalations. Sixteen of 19 patients experiencing asthma of moderate severity obtained moderate to marked relief with two to three courses of 4 to 6 inhalations each. The remaining patients obtained only mild relief. None of the 19 patients failed to obtain some benefit. Sixteen of 21 patients experiencing frequently recurrent paroxysms of severe asthma obtained moderate to marked relief employing one to three courses of 6 to 8 inhalations each. Most of the cases of severe asthma were those requiring treatment in the emergency room of the outpatient department because of failure to respond to the usual procedures and medications used at home. Response was quick in every case, beginning in two to three minutes and reaching its maximum in about five minutes. The optimum dosage in the majority of such cases was about 6 inhalations. The benefit obtained did not appear to be appreciably increased if more than 6 inhalations were given in any one course. It was noted consistently, however, that the duration of the relief produced was inversely proportional to the severity of the asthma, the benefit in the more extreme cases lasting only about fifteen minutes, at which time another series of inhalations had to be given. Patients with milder asthma, on the other hand, reported relief ranging from two to twelve hours. Only 2 patients with severe asthma failed to obtain some benefit from inhaled aludrine sulfate mist.

One of the most gratifying observations with the use of the inhalation route was the low incidence of unpleasant side effects. Of the 48 patients using this method only 2 experienced palpitation, and questioning revealed that in both instances this occurred only after frequent and prolonged use beyond the limits set in our instructions. With cessation of the drug, the palpitation in both cases was mild and fleeting. It was our conclusion that aludrine mist of a 1 : 200 dilution administered as set forth was capable of significant bronchial-dilating action in mild to severe bronchial asthma by way of its local pharmacodynamic effect on contact within the bronchial tree, and that any amount reaching the systemic circulation was of inadequate concentration to produce subjective toxic effects.

One important and unexpected beneficial effect produced by inhalations of aludrine was the decided increase in expectoration in persons with chronic infective (intrinsic) asthma. Patients reported that their sputum was thinner, more abundant and more easily raised. This was an early and consistent finding in all such patients treated by this route. The far reaching importance of this effect is obvious to all familiar with treating this variety of asthma.

Fifteen patients were selected to compare the effects of aludrine and epinephrine administered by inhalation and to state their preference. Aludrine was preferred by 12 patients. Here again patient response and tolerance was found to be widely variable, but all agreed that aludrine acted somewhat more rapidly and that benefit was generally equal to or greater than that produced by epinephrine. Five patients in status asthmaticus of several hours' duration and no longer responsive to epinephrine (1 : 100) inhalations (so called epinephrine-fast) responded promptly to the initial course of aludrine spray. It was the consensus of all concerned that, while the response to aludrine inhalation was quicker than to epinephrine by inhalation or intramuscular injection, or to aminophylline given intravenously, the duration of benefit was definitely shorter than that following the latter drugs.

Anyone desiring to use this drug in solution should be warned of the rapidity with which it becomes oxidized on exposure to air and light. It is best stored in tightly stoppered or sealed amber glass and in a dark place. Exposure to air and light for just a few hours will result in pinkish to brownish discoloration. Such change, however, does not render the drug inert, and many patients claimed that they were unable to detect any lessening of therapeutic effect after the solution had become rather brown in their bottles or nebulizers. These same patients were not benefited by inhalations of saline placebos. Repeated use of discolored solutions by many patients failed to produce any unpleasant subjective or objective response. While the manufacturers are attempting to prepare a more stable solution of this preparation, the property of rapid discoloration should not discourage its use.

### SUBCUTANEOUS ADMINISTRATION

Sterile isotonic solution of aludrine sulfate of a 1 : 1000 dilution was given by subcutaneous injection in doses ranging from 0.1 cc. to 0.5 cc. to 10 patients during paroxysms of severe asthma. Eight of the 10 patients obtained prompt and pronounced benefit; in some instances the relief produced was dramatic. However, every patient receiving this concentration experienced side effects of moderate to marked degree, in some instances sufficiently alarming to preclude the continued use of the drug in a strength of 1 : 1,000. All injections thereafter were of a 1 : 5,000 dilution with doses varying from 0.3 cc. to 0.5 cc. and repeated as warranted.

Sixteen patients experiencing episodes of mild asthma were given 0.3 cc. of aludrine sulfate 1 :5,000. Every patient received prompt and definite relief, generally a complete abolition of the wheezing state. Of 16 patients with asthma which we classified as of moderate severity, 10 obtained decided relief following 0.3 cc. to 0.5 cc. of aludrine 1 : 5,000, 4 obtained only slight relief, and 2 obtained no relief at all. Nine patients with severe prolonged asthma were given this dosage, but in no instance was the relief obtained comparable to that seen in those patients with asthma of less severity. Only 4 of the 9 patients obtained significant benefit and then only after a second dose given fifteen minutes following the first injection. The remaining 5 patients of this last group were either helped not at all or so slightly that the drug was of no value. It should be pointed out, however, that this group consisted of patients notoriously refractory to therapy and generally required a combined therapeutic attack of hospitalization, oxygen inhalation, repeated aminophylline by vein, hypertonic sucrose, etc. With this dosage only 17 of 41 patients (41 per cent) experienced side effects, and in no instance were these of a nature or degree sufficient to render the dosage unsafe or impractical.

It was believed that aludrine sulfate 1 : 5,000 in doses of 0.3 cc. to 0.5 cc. given subcutaneously generally gave a therapeutic effect equivalent to that produced by 0.3 cc. to 0.5 cc. of epinephrine 1 : 1,000 given intramuscularly. Except for the fact that aludrine appeared to have a slightly more rapid onset of action we did not find it significantly superior to epinephrine for use by injection. On five occasions, however, we obtained favorable response to aludrine in patients who failed to receive further asthmadilator action from repeated injections of epinephrine, and we feel that a trial of aludrine (0.3 cc. to 0.5 cc. of 1 : 5,000) is indicated in any patient in the so-called epinephrine-fast state.

The onset of action of aludrine given subcutaneously was apparent in one to three minutes, and its maximum subjective and objective effects generally occurred from five to seven minutes after injection. As with the other methods of administration, the duration of benefit varied inversely with the severity and duration of the asthma. The milder attacks were relieved completely and the patient would report freedom from wheezing for hours to days. Relief afforded the asthmas of greater severity and longer standing generally faded in twelve to fifteen minutes and recourse to repeated injection or supplemental treatment was necessary.

### PHARMACODYNAMICS

*Respiratory.*—Aludrine is but a modified epinephrine, and its action is fundamentaly epinephrine-like; i. e., sympathetic stimulation with resultant inhibition of bronchiolar muscles. The drug is effective when administered by mouth, sublingual absorption, inhalation and injection. Its action is most rapid and effective when it is inhaled in the form of a nebulized mist. Subcutaneously injected aludrine is the second most rapid and the sublinguet third. In many instances buccal absorption is both rapid and extensive enough to make its use beneficial. Aludrine by mouth is the slowest and least reliable. In optimum dosage, as already discussed, its bronchiole-dilating effect is equivalent to that generally observed with therapeutic doses of epinephrine. The increase in vital capacity concomitant with the bronchiole-dilating effect is obvious. This correlation has been studied and reported by Segal and Beakey.[1d] The tendency of aludrine to render bronchial secretions more fluid and thus facilitate the elimination of sputum has been mentioned.

*Cardiovascular.*—On those patients given aludrine by injection observations were made of the cardiac rate and rhythm and blood pressure fluctuations; in some instances electrocardiographic tracings were recorded. Aludrine 1:1,000 was given to 15 patients in doses ranging from 0.1 cc. to 0.5 cc. In every patient but 1 a significant tachycardia resulted, all rates exceeding 100 beats per minute within three to five minutes after injection. While each patient's response was determined by his individual tolerance to sympathomimetic stimulants, it was generally observed that the smaller doses produced a cardiac acceleration of less degree and shorter duration than the larger doses. Rates following administration of aludrine 1:1,000 ranged from 108 to 176, the greater increases resulting from doses of 0.3 cc. to 0.5 cc. The increase in rate usually began ninety to one hundred and twenty seconds following injection. With doses of 0.1 cc. and 0.2 cc. the rate returned to preinjection level within fifteen minutes. With doses of 0.3 cc. to 0.5 cc. the tachycardia persisted from thirty minutes to one hour. Fourteen of the 15 patients reported palpitation of varying degree in association with their tachycardia. (See the section on side actions.)

Ten of the 15 patients experienced an increase in their pulse pressure, the systolic rising from 10 to 30 mm. and the diastolic falling from 10 to 30 mm. Three patients showed no significant change in the systolic reading but a 20 to 30 mm. fall in the diastolic level. Two patients experienced precipitate falls in both systolic and diastolic levels within three minutes after injection. In one 19 year old boy in severe status asthmaticus for thirty-six hours and "fast" to epinephrine and aminophylline a full picture developed of peripheral circulatory collapse (shock) with a drop in blood pressure from 130 systolic and 80 diastolic to 80 systolic and (?) diastolic following an injection of 0.2 cc. of aludrine 1:1,000. The second patient, a 65 year old woman, had a prompt fall in blood pressure from 138 systolic and 80 diastolic to 80 systolic and 40 diastolic after receiving 0.5 cc. of aludrine 1:1,000. She experienced decided weakness, palpitation and generalized tremor, but the shock syndrome did not develop before her systolic pressure gradually rose to 120 systolic and 60 diastolic fifteen minutes later. One patient with hypertension with pretreatment readings of 170 systolic and 110 diastolic gave the following response to 0.3 cc. of aludrine 1:1,000: five minutes, blood pressure 180 systolic and 85 diastolic; fifteen minutes, 175 systolic and 80 diastolic; thirty minutes, 175 systolic and 100 diastolic, and one hour, 150 systolic and 105 diastolic. In all patients the degree and duration of blood pressure changes were in close correlation to the tachycardia produced.

Electrocardiograms were made on 6 patients prior to and following the administration of 0.1 cc. of aludrine 1:1,000. Five of these tracings revealed the development of significant tachycardia following injection of the drug. In no instance was there a disturbance of rhythm. With the exception of an increased rate two of the six tracings were essentially the same before and after drug administration. The other four records showed the following significant changes in configuration:

1. In a 15 year old Negro boy there was a rate increase from 80 to 125; lengthening of P-R interval from 0.10 to 0.12; sagging of $RT_2$ and $RT_3$; upright $T_2$ and $T_3$ changed to a minus-plus diphasic, and lower voltage $T_2$ and $T_3$. 2. In a 43 year old Negro man, the rate increase was minimal, from 115 to 120; P-R interval shortened from 0.14 to 0.12; low $T_1$ changed to isoelectric $T_1$; $T_2$ and $T_3$ to lower voltage, and upright $T_4$ to plus-minus diphasic $T_4$ with coving of S-$T_4$. 3. In a 44 year old Negro man the rate increased from 90 to 110; P-R interval shortened from 0.14 to 0.12; upright $P_1$, $P_2$ and $P_3$ changed to diphasic $P_1$, $P_2$ and $P_3$; isoelectric S-$T_2$ to 1 mm. depression of S-$T_2$, and upright $T_4$ to lower voltage minus-plus diphasic $T_4$. 4. In a 50 year old Negro woman, the rate increased from 80 to 100; P-R interval shortened from 0.18 to 0.14, and upright $T_4$ changed to plus-minus diphasic low voltage $T_4$.

Within two minutes after the injection of 0.1 cc. of aludrine 1:1,000 the 44 year old Negro man (case 3) reported the onset of substernal discomfort of a nature strongly suggestive of coronary insufficiency. This persisted for ten minutes and then spontaneously subsided. It will be noted that the changes occurring in this patient's electrocardiogram following the injection of aludrine are those ascribable to coronary insufficiency and myocardial ischemia.[2] Review of the changes listed will show that all of them are significant positive findings as interpreted by the Master Exercise Test for the demonstration of coronary insufficiency.[3] It will be further observed that such changes occurred in 1 patient (case 2) without a significant coincident increase in heart rate, indicating that the S-T segment and T wave changes seen here are not necessarily the result of concomitant tachycardia. The fact that aludrine in a dose of 0.1 cc. of a 1:1,000 solution is capable of producing the alterations cited, regardless of the condition of the heart prior to administration of the drug, demands the adoption of a weaker solution for routine use and the careful appraisal and selection of patients who are to receive it. In view of these findings it is obvious that aludrine overdosage is of great potential danger in a patient whose myocardium might be partially anoxic by virtue of an attack of bronchial asthma. We are of the opinion that the action of aludrine in these observations is not one of coronary artery constriction but of decided increase in the force of myocardial contraction and a resulting demand for more oxygen, which, of course, is not met.

---

[2] Ashman, R., and Hull, E.: Essentials of Electrocardiography, New York, The Macmillan Company, 1941, chap. 14, pp. 319-329.

[3] Master, A. M.; Friedman, R., and Dack, S.: The Electrocardiogram After Standard Exercise as a Functional Test of the Heart, Am. Heart J. 24:777 (Dec.) 1942.

Because of the high incidence of tachycardia and palpitation, the two occurrences of precipitate drop in blood pressure and the electrocardiographic changes described, aludrine 1 : 1,000 was supplanted by a solution of 1 : 5,000 for subsequent studies. Forty-seven patients were given 0.3 cc. of aludrine 1 : 5,000, and electrocardiograms were obtained on 6 of these prior to and after injection. In spite of the reduction in concentration of the drug 53 per cent of these patients obtained both tachycardia and blood pressure changes. However, in only 2 instances were the changes as great as those following the use of the 1 : 1,000 concentration. The majority of the pulse increases were no more than 10 to 20 beats per minute. In only 3 patients did the rate increase by 30 beats per minute and in 2 patients by 45 beats per minute. The duration of these increases varied from five to ten minutes. We detected only one instance of a disturbance in rhythm, namely the appearance of frequent auricular and ventricular extrasystoles in a 31 year old Negro woman who had a regular sinus rhythm prior to drug administration (case 5). The usual blood pressure changes in this series consisted of a systolic rise of from 10 to 20 mm. without the associated fall in diastolic level so characteristically observed following use of the 1 : 1,000 solution. In general, diastolic levels were found either to remain stationary or to rise from 5 to 10 mm. Blood pressure falls were observed in only 2 patients, in neither case significant: 130 systolic and 90 diastolic to 110 systolic and 85 diastolic and 130 systolic and 80 diastolic to 110 systolic and 70 diastolic. One patient with a pretreatment hypertensive level of 188 systolic and 110 diastolic responded as follows: two minutes after injection 200 systolic and 110 diastolic; five minutes, 180 systolic and 100 diastolic; ten minutes, 185 systolic and 105 diastolic, and fifteen minutes, 185 systolic and 110 diastolic.

Again six electrocardiograms were made prior to and following the subcutaneous injection of 0.3 cc. of aludrine 1 : 5,000. One of the six tracings showed no remarkable change except for a moderate increase in rate. The changes in the other five tracings are as follows:

5. In a 31 year old Negro woman there was an increase in rate from 80 to 125; shortening of P-R interval from 0.16 to 0.12; development of frequent auricular and ventricular premature systoles; change of upright $T_1$ to flat $T_1$, and change of low voltage diphasic $T_2$ and $T_3$ to inverted $T_2$ and $T_3$. 6. In a 50 year old Negro woman there was an increase in rate from 64 to 110; shortening of P-R interval from 0.15 to 0.12, and a change from diphasic $T_4$ to inverted $T_4$. 7. In a 57 year old white man there was an increase in rate from 68 to 80; dipping of $RT_2$ and $RT_3$ segments and $T_4$ of lower voltage and early inversion of downward limb. 8. In a 53 year old Negro man there was an increase in rate from 68 to 74 and a change from a flattened diphasic $T_4$ to an upright $T_4$. 9. In a 47 year old Negro woman there was an increase in rate from 88 to 110, a change from an upright $T_2$ to a flat $T_2$ and from a flat $T_3$ to a slightly inverted $T_3$.

It will be noted that these changes are of the same pattern as those already cited which followed the administration of the 1 : 1,000 concentration. However, with the exception of case 5, the alterations observed with the use of aludrine 1 : 5,000 are proportionately of less degree than those found with the 1 : 1,000 strength. Case 1 is another example of the wide variation in patient tolerance to this sympathomimetic amine. These further observations of the ability of aludrine in 1 : 5,000 concentration significantly to affect cardiac function strengthened our belief in its potential danger if not routinely given in small doses and to selected persons. We are of the opinion that dosage up to 0.5 cc. of a 1 : 5,000 concentration constitutes a safe range when the size of the dose is governed by the age and size of the patient, his tolerance to sympathomimetic stimulants and the severity of his asthma. We observed no cumulative effect or untoward action when these small doses were repeated at fifteen minute intervals.

*Blood Sugars.*—No constant or significant change in blood sugar concentration was found in 6 patients whose blood sugar levels were determined prior to and fifteen minutes after subcutaneous administration of 0.3 cc. of aludrine 1 : 5,000.

The levels were as follows:

| Case | Before Drug | After Drug |
|---|---|---|
| 1 | 83 | 75 |
| 2 | 77 | 69 |
| 3 | 71 | 71 |
| 4 | 100 | 87 |
| 5 | 69 | 73 |
| 6 | 91 | 100 |

## SIDE EFFECTS

The incidence of subjective side effects varied with the method of administration as in the accompanying tabulation.

| Method and Dose | Percentage |
|---|---|
| Sublingual, 10 mg. | 33 |
| Oral, 25-50 mg. | 80 |
| Oral, 15 mg. | 75 |
| Inhalation, 1 : 200 | 4 |
| Subcutaneous, 1 : 1,000 | 100 |
| Subcutaneous, 1 : 5,000 | 41 |

While the incidence was relatively high (33 per cent) with use of the sublinguets, the side actions were usually mild and fleeting. Two patients reported mild precordial aching in association with their palpitation, and though the degree of the discomfort was not alarming we advised against the further use of the drug. Three others reported headache, 2 reported nausea and 1 experienced nervousness, but here again the symptoms were merely unpleasant and never distressing. Because of the low incidence and comparative mildness of their side effects the sublingual and inhalation methods of administration were most favored by both doctors and patients. In our hands the occurrence of unpleasant side actions of varying degree in well over the majority of patients taking the drug orally rendered this method of administration impractical. While reduction in the size of the oral dose lessened the severity and duration of the side effects it made no significant difference in their incidence. The nature and degree of side effects following subcutaneous injection in every patient given a 1 : 1,000 concentration made this route and dosage unsafe. Reduction in the drug concentration to a 1 : 5,000 solution reduced the incidence of subjective side actions by more than half and showed such dosage to be safe and practical if reasonable care is taken in selection of patients.

The side effects observed are given in the accompanying list in their decreasing order of frequency.

| Side-Effect | Percentage of All Side-Effects |
|---|---|
| 1. Palpitation | 90 |
| 2. Nausea | 19 |
| 3. Headache | 17 |
| 4. Nervousness | 16 |
| 5. Tremor | 14 |
| 6. Dizziness | 13 |
| 7. Precordial ache | 9 |
| 8. Weakness | 7 |
| 9. Sweating | 7 |
| 10. Anginal pain | 3 |
| 11. Epigastric pain | 3 |
| 12. Vomiting | 3 |
| 13. Tinnitus | 3 |
| 14. Flushing of face | 1 |
| 15. Diarrhea | 1 |

The severity and duration of these symptoms were generally in direct proportion to the size of the dose given. However, there were a few patients exhibiting unusual sensitivity to the drug, and in these the side effects were aways alarming with minimal effective doses. It was our observation that, in general, side effects did not tend to decrease in severity or incidence on repeated use of the drug in the same patient.

*Side Effects of Serious Import.*—Three patients experienced acute episodes of typical coronary insufficiency pain, 2 after taking aludrine by mouth, and 1, already reported, after 0.1 cc. of aludrine 1 : 1,000 subcutaneously (case 3 of the first series of electrocardiograms).

Case 10.—A 45 year old Negro woman, hypertensive, after three oral doses of aludrine, 25 mg. each, six hours apart, experienced an episode of substernal pain with radiation into teeth, both arms and hands, lasting from twenty to thirty minutes. She had not had angina prior or subsequent to use of aludrine.

Case 11.—A 37 year old Negro woman, after one oral dose of aludrine of 25 mg. and four doses of 50 mg. each, all three to three and one-half hours apart (used to abort recurring asthma) experienced sharp substernal pain with radiation across left precordium and into left arm to elbow, lasting about five minutes. She had not had angina prior or subsequent to use of aludrine.

Nine patients reported precordial ache or "heart soreness," in each instance accompanying palpitation of moderate to marked severity and duration. In 5 of these cases the disturbance followed oral doses of 25 mg. or greater; 3 instances followed use of the 10 mg. sublinguet, and 1 occurrence was precipitated by frequent and prolonged inhalation of aludrine 1 : 200 nebulized mist. All of these patients were in the 40 to 60 year age group.

The single case of sudden shock has already been noted. It occurred in a 19 year old white male, in status asthmaticus for thirty-six hours and "epinephrine fast," following subcutaneous injection of 0.2 cc. of aludrine 1 : 1,000. Within three minutes he was in profound shock, with marked pallor, weakness, sweating, vomiting, a blood pressure fall from 130 systolic and 80 diastolic to 80 systolic and (?) diastolic and a pulse increase from 92 to 120. He responded promptly to 0.5 cc. of epinephrine 1 : 1,000 given intramuscularly.

The blood morphology was studied in 10 patients prior to and after continual oral use of aludrine for periods ranging from four weeks to three months, and no significant alterations of the blood picture were found in any case.

### SUMMARY AND CONCLUSIONS

Isopropylepinephrine, 1-(3-4 dihydroxyphenyl)-2-isopropyl-amino-ethanol (aludrine) is a sympathomimetic amine capable of bronchial-dilating action in bronchial asthma when administered by mouth, sublingual absorption, inhalation and subcutaneous injection.

There is wide variation among patients in both therapeutic response and occurrence of side actions.

The inhalation of a nebulized mist of aludrine 1 : 200 proved to be the best method of administration, generally affording relief in asthma of all severity with an incidence of side effects of only 4 per cent. Aludrine in this form greatly facilitated the liquefaction and excretion of sputum in chronic asthma.

Sublingual absorption of 10 mg. pellets is the second method of choice because of its convenience, speed of action and the fact that the patient can discard all undissolved drug in the event of serious side effects. The sublinguet is of greatest value in the early abortion of mild asthma. It is of less benefit in moderate asthma and of no benefit in severe asthma. It causes mild and fleeting side actions in 33 per cent of users.

The routine use of aludrine by mouth is impractical because of the high incidence of side effects (75 per cent) with use of the minimum effective dose (15 mg.). In general, the relief afforded does not justify the unpleasant symptoms associated with its administration.

The high incidence of pronounced side effects and the demonstration of electrocardiographic pattern changes are indicative of the potential danger in the use of aludrine of 1 : 1,000 concentration subcutaneously. In selected patients doses of 0.3 cc. to 0.5 cc. of aludrine 1 : 5,000 are safe and practical, with a therapeutic efficacy about equivalent to the customary doses of epinephrine 1 : 1,000.

Experience has shown that aludrine by inhalation and injection is effective in those patients no longer responding to epinephrine, the so-called epinephrine fast.

Aludrine in 1 : 1,000 concentration given subcutaneously causes marked tachycardia and increase in pulse pressure, with moderate rise in systolic and fall in diastolic blood pressure levels. Aludrine in 1 : 5,000 concentration causes a slight increase in cardiac rate and a slight elevation of systolic blood pressure, the diastolic generally remaining constant.

Overdosage of aludrine given by mouth or subcutaneous injection and therapeutic doses given by the same routes to sensitive persons are capable of producing symptomatic and electrocardiographic evidence of coronary insufficiency. Aludrine in therapeutic doses administered sublingually and by inhalation gave no subjective evidence of coronary insufficiency.

Aludrine in therapeutic dosage does not significantly alter blood sugar concentration.

Side effects are relatively common with every method of administration except inhalation. Their nature and incidence are discussed. Serious side actions of anginal pain, precordial ache and shock are noted.

Aludrine displayed no damaging effect on the blood picture of 10 patients using it orally for prolonged periods.

## POLITICS IN SCIENCE AND IN GENETICS

Genetics, which is established as a science, has again become a whipping boy for political philosophy. Repeatedly in history politicians try to misuse the observations of genetics to distort truth as a buttress for political beliefs. Hitler, aided by German pseudoscientists, attempted to prove theories of racial superiority. Heredity and gene inheritance was all and environment nothing; therefore purification of race demanded elimination of all gene influences other than those of purely Aryan derivation, ridiculous and impossible as was that objective. Now in Russia equal and opposite claims are made (i. e., heredity and gene inheritance mean nothing and environmental influences are all). Dr. H. J. Muller, Nobel Prize winner for work in genetics, and Sir Henry Dale, former president of the British Association for the Advancement of Science, have resigned from the Academy of Sciences of the U. S. S. R. Their resignations were submitted in protest against the frontal attack on science made in the recent decision of the Central Executive Committee of the Communist Party. The entire science of genetics based on the theories of Mendel and Morgan was repudiated. On the surface, the controversy in Russia relates to two scientific positions regarding genetics: Mendel's theories of gene inheritance and the noninheritance of acquired characters, and the opposite view, the rejection of the part played by genes in heredity and acceptance of inheritance of acquired characteristics. The scientific aspects of both points of view are clear, and the evidence is considered sufficient for a proper scientific choice between the alternatives.

Classical geneticists have accepted Mendel's ideas and demonstrated these ideas times without number. T. D. Lysenko, however, who represents the Russian point of view, insists that classical ideas are all wrong. He states that valuable crop plants can be improved by bettering the environment and that these improvements are subsequently transmitted to the plant offspring. Lysenko adds that, since classical ideas have been demonstrated to be wrong, any one who persists in adhering to them is guilty of sabotage of the Soviet State.

At the August 1948 meeting at the Lenin Academy of Agricultural Sciences, Lysenko's ideas were officially approved by the Central Executive Committee of the Communist Party. The committee stated that Lysenko's ideas were in accord with the Bolshevik party's political philosophy. Several of Lysenko's opponents therefore confessed their error and made public recantation of their so-called scientific heresies; other scientists were dismissed from scientific positions. As far as Russia was concerned, a scientific difference of opinion was settled by political decree.

A report on the Russian attitude toward genetics in the December 1948 *Bulletin of the Atomic Scientists*[1] points out that the controversy lacks a real scientific basis. Because Soviet politicians had proved themselves unwilling or unable to grasp the technicalities of genetic reasoning, they had taken a dislike to its conclusions for motives of their own. The fact that the politicians were unable to secure any well known geneticist to sponsor a point of view directly opposed to the classical beliefs led to the selection of Lysenko, a plant breeder without special renown, as a scientific stooge through whom political propaganda could flow. The report states that Lysenko's education and experience in genetics "gives him no more claim to being a geneticist than does doctoring dogs for worms."

The political stake of Communist Russia in genetics is an obvious one. All Russian scientists must subscribe to the Doctrine of Dialectical Materialism,[2] which implies that (1) everything is material (2) matter is eternal but is always changing and (3) matter is composed of opposing elements whose interaction is the cause of change. In the field of genetics this presumably fits Lysenko's ideas. Pure lines inevitably degenerate (matter always changes); mutations can be induced by environment; characters best adapted to the environment are dominant, and crosses within a pure line restore vigor. As these ideas are generally not in accord with classical genetics it supposedly follows that chromosomes and genes can have nothing to do with heredity and these theories should be abolished. Lysenko's ideas also are in accord with dialectical materialism in human genetics, which must permit the belief that all humans are born as a *tabula rasa,* i. e., a clean slate on which anything may be written by environment. This last thereby permits a belief in Soviet promises of a future politicosocial utopia. In a democracy which respects the scientific demonstrations of classical genetics each person cannot be promised equal genetic inheritance, but only equal opportunity under the law. Soviet political pseudogenetics, however, permits a promise of equal birth inheritance to all. Whenever scientific decisions are made for political purposes rather than on the basis of scientific evidence, the inevitable loser is mankind itself.

## SYRINGE-TRANSMITTED HEPATITIS

An editorial in the Sept. 22, 1945 issue of THE JOURNAL[1] pointed out that the data with regard to syringe-transmitted infection are in accord with what is known about hepatitis transmitted by the injection of yellow fever vaccine containing dried human plasma, of measles or mumps convalescent serum and of blood in transfusions. In all these conditions injection of presumably infected human blood or plasma has been followed by cases of hepatitis two or four months later. Darmady and Hardwick[2] found among 182 consecutive patients with jaundice admitted to their hospital that 34 had received intravenous or intramuscular injections within the previous two hundred days. These authors stress two points in the prophylaxis of syringe hepatitis: First, the quantity of icterogenic principle involved may be extremely small and can be harbored in any syringe. Thus Bradley, Loutit and Maunsell[3] produced jaundice in human subjects by the administration of as little as 0.1 cc. of homologous serum. Secondly, this agent is heat resistant and is not killed by the ordinary methods of sterilization.

Morton[4] reports 64 cases of hepatitis among 338 men treated in a venereal disease clinic. Incubation periods ranged from one hundred to two hundred days and over. The sterilizing capacity in the clinic was found to be inadequate and the number of syringes insufficient to allow proper cleaning and sterilizing.

Malmros[5] and his co-workers suggest that the term "homologous serum jaundice" be changed to "inoculation hepatitis," since the virus is already present in the blood during the preicteric period and can be transferred not only with the serum, but also with plasma and whole blood. Malmros observed in 1923 an epidemic of hepatitis among diabetic patients treated in the Medical Clinic of Lund. An exhaustive study established that the virus of the disease had been transferred by inoculation from one patient to another in connection with samplings for blood sugar analyses.

Mendelssohn and Witts[6] demonstrated in an experiment the risk of introducing infection from venepuncture with syringes that are washed but not sterilized. With a syringe containing methylene blue they punctured a rubber tube through which water was running, pointing the needle in the same direction as the water was flowing. As soon as the negative dynamic pressure caused by the flow of water became higher than the hydrostatic pressure, the contents of the puncturing syringe were drawn by suction into the water flowing through the rubber tube, staining the water blue. Malmros and his co-workers confirmed this experiment by using a more sensitive indicator, namely, a 20 per cent sodium fluorescein solution. When blood is taken from a vein with a syringe by the orthodox technic, some of the blood is sucked back into the vein when the tourniquet is released. If the syringe is not sterile, the patient is exposed to infection. These authors suggest that the risk of infection can be eliminated in two ways: (1) by the use of sterile needles alone without syringes at venepuncture; (2) by the provision of a sufficient number of syringes so that a fresh sterilized instrument is used for every patient.

## THE JOSEPH GOLDBERGER AWARD IN NUTRITION

Until recently progress had been slow in efforts to define chemically the active anti-pernicious-anemia principle of liver. The absence of a suitable experimental analogue to pernicious anemia has made it necessary to test various chemical fractions by laborious clinical assay. Now another assay has been devised, a microbiologic technic, for anti-pernicious-anemia potency. This method is yet in the developmental stage. Few clinical investigators have had the patience to study the activity in the human being of fraction after fraction from liver over the long interval necessary for the successful concentration of the active principle.

Within a year after Minot and Murphy's report[1] of the successful treatment of pernicious anemia with a diet containing large quantities of liver, Dr. Randolph West[2] embarked on an attempt to concentrate the active principle from liver. Dr. West's continuous interest in this problem is attested by repeated publications with various collaborators during the intervening twenty-one years. These studies led to the characterization of an active, but impure, concentrate as a peptide in some respects resembling an albumose, and free of glucosamine.[3] The more purified of these products was active in quantities of 20 to 25 mg.

Finally, in April 1948, this persistent investigation by West culminated in the brief announcement[4] that doses as small as 6 micrograms of the newly isolated vitamin $B_{12}$[5] exhibited striking hemopoietic activity in pernicious anemia. These results have been confirmed by several groups of workers. This new vitamin is a potent hemopoietic agent in the three macrocytic anemias associated with megaloblastic arrest of the marrow–pernicious anemia, sprue and nutritional macrocytic anemia. Of further great importance is the evidence[6] that vitamin $B_{12}$ is effective in alleviating the reversible neurologic changes of combined system disease. The demonstration of the clinical activity of this new vitamin in human diseases and its identification with the anti-pernicious-anemia factor in liver extract is a major achievement in clinical nutrition and is one which the Award Committee of the American Medical Association regards as of such preeminent accomplishment that Dr. West has been selected to receive the first Joseph Goldberger Award in Clinical Nutrition.

## Current Comment

### GOVERNMENT MEDICINE AND THE NAVAJO-HOPI INDIANS

Last week The Journal published a special report on medical conditions among the Navajo-Hopi Indians, made by a group of physicians sent by the Department of the Interior as representatives of the American Medical Association. These physicians spent two weeks traveling over the Indian reservations inspecting and studying health conditions. The medical care of these 64,000 Indians, roaming over some 18,000,000 acres of eroded land, appears to be most unsatisfactory. The statistical data available regarding tuberculosis indicated that the mortality of this disease among the Indians is about ten times that of the general population. Other serious medical problems are the upsurging venereal diseases, particularly syphilis, preventable killing diarrheas and trachoma which might be eliminated by an intensive treatment campaign. There are also many surgical, orthopedic and dental problems. The report of the physicians stressed the common preventable, communicable and curable diseases because, the report said, they best revealed the inadequacy of past and present medical services. Their numerous recommendations made to improve the health of the Navajo-Hopi Indians amount in brief to a complete revamping of the medical system in that area. The committee recommended particularly that the Indian Medical Service be free from the handicaps inherited under the Civil Service Act, including salary and age limitations. Good physicians cannot afford to serve without initiative and freedom of action. Thus, there is already, in our country, a striking example of the failure of government management of medical affairs.

### DRIVE TO OBTAIN PHYSICIANS FOR ARMED FORCES RECOMMENDED

A nationwide drive for volunteers to relieve the critical shortage of physicians and dentists in the armed forces was recommended February 5 to Secretary of Defense James Forrestal. The project was proposed by the recently appointed Armed Forces Medical Advisory Committee. It would be directed mainly toward approximately 15,000 young men who were deferred from service in order to complete their professional training—many at government expense. The Committee recommended that an appeal be made for volunteers from among these men to avoid the necessity of asking Congress for additional legislation to meet critical needs of the armed forces. The program will be conducted by the Medical Advisory Committee with the cooperation of the medical and dental professions and the medical services of the Army, Navy and Air Force. It is estimated that by the end of July there will be a shortage of medical officers in the armed services of about 1,600 physicians and about 1,160 dentists and that by the end of the year the combined shortage will total approximately 2,200 physicians and 1,400 dentists. The medical profession should respond to this appeal with the spirit that has been traditional in American medicine. Thus the medical profession will show that it merits the freedom that it now seeks to maintain.

### UNDECYLENIC ACID AND PSORIASIS

Elsewhere in The Journal (p. 444) is an article on the use of undecylenic acid in the treatment of ringworm, psoriasis and neurodermatitis. Many treatments have been proposed for psoriasis but none have proved generally effective. The skin manifestations are controlled in many instances, but usually the sufferer returns to the physician complaining of recurrence of the disease. Seasonal variations, response to sunlight, the use of potent drugs for internal use or application to the skin, and other factors have provided, at times, more confusion than knowledge concerning the cause and treatment of psoriasis. Thus, there is not today one drug or method of treatment that can be regarded as specific for the control, let alone cure, of this affliction. For this reason, if no other, a technic or remedy that offers promise is worthy of study to determine its true usefulness. If it proves to be a worth while addition to the medical armamentarium, its usefulness will become established promptly. If, however, it eventually proves disappointing, the failure should be revealed in its true light. The use of undecylenic acid in the treatment of psoriasis and neurodermatitis offers an interesting approach to the control of these problems. The method is still in the stage of experimental investigation and must be so regarded until further evidence is accumulated. Under no circumstances should it be accepted at this time as the most effective and only treatment.

# ORGANIZATION SECTION

## Official Notes

### TOWN MEETING BROADCAST ON COMPULSORY SICKNESS INSURANCE

Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, and U. S. Senator H. Alexander Smith, Princeton, N. J., will speak against a national compulsory sickness insurance program for the American people on America's Town Meeting of the Air, on Tuesday night, Feb. 22, 1949. The program will be broadcast and televised from 8:30 to 9:30 p. m., Eastern standard time, over American Broadcasting Company networks. Senator Smith, a Republican, is a member of the Senate Labor and Public Welfare Committee and former chairman of the Senate Sub-Committee on Health. Federal Security Administrator Oscar Ewing and Walter Reuther, Detroit, president of the United Automobile Workers, C. I. O., will speak in favor of a national compulsory sickness program. The forum will be moderated by George V. Denny Jr., president of Town Hall, New York.

### APPOINTMENT TO BUREAU OF HEALTH EDUCATION

Dr. Donald A. Dukelow, Minneapolis, director of public health education for the Minnesota Department of Health, 1937-1945, has accepted an appointment effective in March to become medical consultant on health and fitness in the Bureau of Health Education of the American Medical Association. He will deal particularly with school health programs. For the past three years Dr. Dukelow has been director of health and medical care division, Community Chest and the Council of Hennepin County.

## Washington Letter

*(From a Special Correspondent)*

Feb. 7, 1949.

### Sickness Insurance "Debated" in *Congressional Record*

Although it probably will be weeks, and more likely months, before the issue of compulsory sickness insurance reaches the stage of open debate on House or Senate floors, the daily *Congressional Record* is serving as a pro and con forum on the question in the interim. In the issue of January 18, for example, Senator Pepper—one of the most articulate proponents of Murray-Wagner-Dingell legislation—had published in the *Record* a guest column which he had written for the Alexandria (Va.) *Gazette*.

"None of us is in favor of socialized medicine," says the Pepper article. "All of us want to see our national health system continue to expand as an integral part of our system of free enterprise with the assistance and encouragement of our federal state and local governments. We will see that this is done."

The *Congressional Record* of January 13 carried items inserted by Representatives Smith (Ohio) and Stefan (Neb.), the former warning against the type of insurance proposed by the Federal Security Agency and the latter giving a first hand account of the workings of Britain's nationalized health service. They were, respectively, the text of a radio broadcast by a San Francisco attorney, Aaron M. Sargent, entitled "Socialized Medicine," and an article entitled "State Medicine in Practice" which was originally published in the *Christian Science Monitor*.

### Senator Hill Considering a Substitute National Health Bill

Although he is classed as a Democratic "regular," who generally is in agreement with Truman administration policies, Senator Lister Hill (Democrat, Alabama) has let it become known that he is favorably impressed by a national health plan designed to obviate compulsory sickness insurance. The plan was submitted to him by Dr. Gilson Colby Engel, president of the Medical Society of the State of Pennsylvania. Its provisions, in brief, are: (1) establishment of a federal Department of Health, headed by a doctor of medicine who would serve as a Secretary in the President's Cabinet; (2) removal of partisan politics from appointments to the department; (3) consolidation of the military medical services; (4) promotion of health education programs in cooperation with state and local medical societies; (5) federal support of medical research; (6) financial aid to medical students on condition that they agree to practice at least five years in rural areas; (7) financial assistance to student nurses; (8) federal support of Blue Cross and Blue Shield plans for the ultimate benefit of the medically indigent; (9) expansion of hospitals and diagnostic centers in rural areas, and (10) expansion of mental hygiene clinics.

The fact that Senator Hill is giving serious attention to the Engel plan derives particular significance from his strategic—and unique—position as a member of both the Labor and Public Welfare Committee and the Appropriations Committee. The former is in charge of the Murray-Wagner-Dingell bill, along with virtually all other health and medical bills, and the latter committee is the one that passes on all expenditures. Furthermore, Senator Hill has just been added to the subcommittee that will handle the 1949-1950 budget of the Federal Security Agency, "parent" body of U. S. Public Health Service, and which would administer any compulsory insurance plan that might be enacted. Alabama's senior senator is the only member who sits on both the Labor-Public Welfare and Appropriations Committees. On January 24 he introduced S. 614, which provides for the most extensive amendment of the Hill-Burton Hospital Survey and Construction Act since its enactment, increasing the annual federal contribution to $150,000,000 and otherwise enlarging assistance to the states and to private nonprofit institutions. On January 27 he went to Birmingham, Ala., to participate in dedication of the first major health center to be completed under provisions of the Hill-Burton Act.

### 32 New Members of Study Sections at National Institutes of Health

Thirty-two medical and biologic scientists have joined seventeen research study sections of the National Institutes of Health, replacing members whose terms expired Dec. 31, 1948. The appointees are as follows: antibiotics, Drs. Arthur P. Richardson (Emory) and Harry H. Gordon (Colorado); bacteriology, Drs. Morris F. Shaffer (Tulane) and Charles E. Smith (Stanford); biochemistry and nutrition,. Drs. William J. Darby (Vanderbilt) and Wendell H. Griffith (Texas); cardiovascular, Drs. John K. Lewis (Stanford), George E. Burch (Tulane) and W. C. Stadie (Pennsylvania); dental, Drs. Allan G. Brodie (Illinois) and Thomas J. Hill (Western Reserve); hematology, Dr. Louis K. Diamond (Children's Hospital, Boston); malaria Drs. John M. Henderson (Columbia) and George H. Boyd (Georgia); metabolism and endocrinology, Drs. Arthur Grollman (Southwestern) and Samuel Soskin (Michael Reese, Chicago); pathology, Drs. Douglas H. Sprunt (Tennessee) and Russell L. Holman (Louisiana State); pharmacology, Drs. Carl A. Dragstedt (Northwestern) and Harvey B. Haag (Medical College of Virginia); physiology, Dr. Howard B. Lewis (Michigan); public health, Drs. Carl Buck (Michigan) and Donal Sheehan (New York Univ.); radiobiology, Drs. Simeon T. Cantril (Swedish Hospital, Seattle) and Robert R. Newell (Stanford); sanitation, Drs. Rolf Eliassen (New York Univ.) and Harold B. Gotaas (California); syphilis, Dr. Malcolm H. Merrill (California State Dept. of Public Health); tropical diseases, Drs. Asa C. Chandler (Rice Institute) and P. Morales Otero (Univ. of Puerto Rico), and virus and rickettsial, Drs. John H. Dingle (Western Reserve) and William F. Friedewald (Emory).

# Medical Legislation

## STATE LEGISLATION

### Arkansas

**Bills Introduced.**—H. 96 proposes to make it **unlawful to sell isonipecaine, barbital and benzedrine** except in drug stores licensed by the State Board of Pharmacy and except upon written prescriptions by persons licensed in Arkansas to practice medicine and surgery, osteopathy, dentistry and veterinary medicine. H. 159, to amend the basic science act, proposes to **exempt** therefrom **any person who was licensed to practice** the healing art in the state of Arkansas prior to March 22, 1918.

***Bills Passed.***—*H. C. R. 4 passed the Senate January 25.* It memorializes Congress not to enact any proposed legislation the effect of which will be to bring the **practice of medicine** in this country **under federal direction and control**, either through a form of compulsory insurance or any system of medical care designed for national bureaucratic control.

### California

**Bills Introduced.**—A. 764, to amend the Labor Code, proposes that the articles thereof relating to **employment of aliens** shall not apply to the employment by a county of an intern or resident physician for services in the county hospital under an exchange arrangement with medical facilities in foreign countries. A. 766, to amend the business and professions code, proposes to authorize the employment of two **investigators for the Board of Medical Examiners.** A. 863 proposes the enactment of a law providing a system of **prepaid health service.** S. 277, to amend the business and professions code, proposes the enactment of a **physical therapists practice act** and authorizes the Board of Medical Examiners to grant registration to such practitioners. Physical therapy is defined to mean "the treatment of any bodily or mental condition of any person by the use of the physical, chemical, and other properties of heat, light, water, electricity, massage, and active and passive exercise. The use of roentgen rays and radium, for diagnostic and therapeutic purposes, and the use of electricity for surgical purposes, including cauterization, are not authorized under the 'physical therapy' " as used in this proposal. S. 329 proposes the creation of a **Board of Naturopathic Examiners** with power to issue certificates designated "Naturopathic physician's certificate." This certificate would authorize the holder to diagnose and treat all human ailments and abnormalities by the use of such forces and substances as light, air, water, clay, heat, rest, diet, herbs, electricity, massage, Swedish movements, suggestive therapeutics, magnetism, physical and mental culture. S. 343, to amend the business and professions code, proposes the creation of a California **State Hearing Aid Board** to issue certificates to hearing aid specialists, defined as meaning persons "certified and licensed to make fittings of hearing aids for persons suffering from deafness and to sell hearing aids and hearing aid supplies at retail."

### Connecticut

**Bills Introduced.**—H. 138, to amend the law relating to privileged communications, proposes that no person authorized to practice medicine or surgery shall be compelled **to disclose in any legal proceeding any information** which he may have acquired in attending any patient in his professional capacity, without the consent of said patient, which information was necessary to enable him to prescribe for such patient as a physician, or to do any act for him as a surgeon. H. 161 proposes to require each physician to report immediately to the State Department of Health, in writing, the name, age and address of each person known to him to be subject to **recurrent attacks of epilepsy** in any of its forms or to recurrent periods of unconsciousness uncontrolled by medical treatment. H. 210 proposes the creation of a Board of **Examiners for X-Ray Technicians** with authority to issue to successful applicants a certificate of registration as an x-ray technician, which shall constitute a license to practice x-ray technology as a technician under the direct supervision of a licensed doctor of medicine, dentist or osteopathic physician. The practice of x-ray technology is defined by the proposal as the performance for compensation received or charged of services in the diagnostic or therapeutic application of x-rays or other ionizing radiations in the field of medicine. S. 130 proposes to authorize any local health officer of a town, city or borough to grant licenses for **the practice of massage** within his jurisdiction and defines massage as being "any process or action of conjoint motion and pressure applied by hand, such as rubbing, stroking, kneading, tapping or other similar manipulation, with or without the application of cream, lotions, or linaments, or the use of hand vibrators or rollers to any part of the human body for purpose of relieving pains, aches, stiffness, or soreness of muscles or for the purpose of stimulating blood circulation or reducing conditions of obesity, including the use of vapor treatments and any and all other manual means such as physical exercises for the conditioning of the human body."

### Georgia

**Bill Introduced.**—H. 9 proproses to direct the State Department of Public Welfare to formulate and put into effect plans and programs and facilities for the care and treatment of children residing in Georgia **suffering from cerebral palsy** and all other handicapping conditions.

### Indiana

**Bills Introduced.**—H. 64 proposes that in any action to determine who is **the father** of any child, the court, on motion of either party, shall order the mother, her child and the defendant to submit to one or more blood grouping tests by a duly qualified physician, to determine whether or not the defendant can be excluded as being the father of the child, and the results of such tests may be received in evidence but only in cases where definite exclusion is established. S. 32 proposes to make it **unlawful to practice psychiatry** or to act as an alienist or to treat psychiatrically or subject to the influence of psychiatric examination and treatment any person without first having received from a recognized medical college the degree of Doctor of Medicine and having further received from the Board of Medical Registration and Examination of Indiana a certificate authorizing the practice of medicine.

### Iowa

**Bill Introduced.**—S. 181 proposes to require all physicians to report immediately to the local health officer in writing the name, sex, date of birth and address of every person diagnosed as having **epilepsy or similar disability** characterized as "momentary or prolonged lapses of consciousness or control which is, or may become chronic."

### Maine

**Bill Introduced.**—H. 476 proposes the creation of a board of trustees of the **state fund for alcoholics** and directs the board to study the problem of alcoholism, including methods and facilities available for the care, custody, detention, treatment, employment and rehabilitation of persons addicted to the intemperate use of spirituous or intoxicating liquors.

### Massachusetts

**Bill Introduced.**—S. 396 proposes to repeal all laws requiring **vaccination.**

### Michigan

**Bill Introduced.**—S. 58 proposes a bill to provide **central records and business accounting,** to coordinate the issuance of licenses and to achieve maximum economies in the utilization of space, personnel and records used by the several licensing and examining boards, including the Board of Examiners of Basic Sciences, Board of Chiropractic Examiners, the Board of Registration in Medicine and the Board of Osteopathic Registration and Examination.

### Minnesota

**Bills Introduced.**—H. 156 proposes regulations for the incorporation of **voluntary nonprofit medical and hospital care associations.** H. 183 proposes to **authorize persons to dispose of their body** in whole or in part by will to a teaching institution, university, college, state board of public health, or legally licensed hospital, either for use as such institution, university, college or hospital may see fit, or for such use as may be expressly designated in the will.

### Montana

**Bills Introduced.**—H. 115 proposes the creation of a **State Board of Practical Nurses** and defines the practice of practical nurses as follows: "A person practices practical nursing within the meaning this act when, for compensation or personal profit, she or he performs such duties as are required in the physical care of convalescent or chronically ill or aged or infirm patients or those suffering from minor ailments in hospital or home under the supervision and direction of qualified physicians or who assist registered nurses in the care of acutely ill patients in hospital and home under the direction of qualified physicians. S. 17 proposes to include 'isonipecaine, amidone, isoamidone, ketobemidone" within the definition of "**narcotic drugs.**"

### New York

**Bills Introduced.**—A. Res. 27 proposes the creation of a joint legislative committee to make a survey and study of the physical, social and educational **problems resulting from rheumatic fever.** A. 228 and S. 310, to amend the pharmacy law, propose to make it **an act of unprofessional conduct** for a pharmacist to enter into an agreement with a physician, dentist, podiatrist or veterinarian for the payment or acceptance of compensation in any form for the recommending of the professional services of either party. A. 275 and S. 270, to amend the education law, propose to direct the board of education of each city and each school district maintaining public schools to provide **adequate health services for pupils** attending such schools. Such service shall include, among other things, facilities to afford adequate physical examinations, including x-raying of the chest of all pupils annually. A. 400 and S. 364 propose to direct the state university trustees to establish a **school of medicine** in the county of the Bronx. A. 429, to amend the education law, proposes to make **the use of x-rays** for diagnostic or therapeutic purposes the practice of medicine and to regulate the use of such practices. S. 64 proposes to make it **unlawful** for any public or semipublic hospital, supported wholly or partly by public funds, to **refuse to permit any physician or surgeon** duly licensed by the state to diagnose, treat or operate on any patient in any such hospital or to refuse admission to any such hospital of any patient who has been recommended to be sent to or who has been sent to any such hospital by any such physician or surgeon. A. 496 and S. 412 propose the creation of a state commission to initiate, formulate and execute a master plan for the promotion **of mental health programs.** A. 558, to amend the education law, proposes to make it the duty of each medical inspector having jurisdiction over any public school in the state to examine each pupil attending such school for **symptoms of tuberculosis** at least once each year. A. 590, to amend the mental hygiene law, proposes the establishment of minimum standards for the staffs needed for the operation of **state mental hospitals.** A. 661, to amend the mental hygiene law, proposes to eliminate from the existing law the requirement that the **directors of the homeopathic hospitals** for the mentally ill shall be homeopathic physicians and that preference in such institutions shall be given to homeopathic physicians. S. 389 proposes payment of **subsidies to student nurses.** S. 497 and A. 571, to amend the mental hygiene law, propose the creation within the department of mental hygiene of a **bureau of alcoholic rehabilitation** to establish and equip hospitals, clinics, custodial institutions or farms in connection either with existing hospitals or other institutions with the facilities for the diagnosis, classification, hospitalization, confinement and treatment of persons who are found to be alcoholics.

### North Dakota

**Bills Introduced.**—H. 122 proposes to permit applicants for a license to practice medicine and surgery to take such **examination** in any one of the following **foreign languages:** Scandinavian, German, Czechoslavakian, Polish and French. The proposal would further provide that lack of American citizenship and residence shall be no bar for license to practice medicine in the state. S. 127 proposes regulations for the **establishment and regulation of rural hospitals,** community clinics, health stations, first aid stations and the training of interns, nurses and other health workers, together with facilitating the placement and training of physicians and surgeons in the state. S. 144 proposes that the **superintendent of the state hospital** must be a competent business executive rather than a graduate of a reputable medical college and a physician of acknowledged skill and ability.

### Ohio

**Bill Introduced.**—H. 21 proposes that in an action or proceeding where **the physical condition of a party** is in issue the court may, on application of an adverse party, order said party to submit to a physical examination by a licensed physician approved by the court, on condition that said physician make a written report of his examination and furnish the party examined with a signed copy of such report and that such physician file the original report with the court in said action or proceeding, unless the party examined shall in writing waive the right to have said original report filed.

### Oregon

**Bills Introduced.**—S. 40 proposes an act for the **licensing of practical nurses** and defines practical nursing as "the performing by any person for compensation or personal profit services in the nursing or care of the sick, not requiring specialized education, knowledge or skill equivalent to that of a graduate or registered nurse. S. 54, to amend the income tax law, proposes to authorize **the deduction of expenses paid** during the taxable year, not compensated for by insurance or otherwise, for medical care of the taxpayer, his spouse, or a dependent, to the extent that such expenses exceed 5 per cent of the adjusted gross income. The term "medical care" in the proposal would include amounts paid for the diagnosis, cure, mitigation, treatment or prevention of disease or for the purpose of affecting any structure or function of the body (including amounts paid for accident or health insurance).

### Pennsylvania

**Bills Introduced.**—H. 18 proposes regulations for the licensing and **registration of registered and practical nurses.** The practice of nursing as a registered nurse is defined as the performance for compensation or personal profit of any professional service requiring the application of principles of nursing based on biologic, physical and social sciences such as responsible supervision of a patient requiring skill in observation of symptoms and reactions and the accurate recording of the facts and carrying out of treatments and medications as prescribed by a licensed physician and the application of such nursing procedures as involve understanding of cause and effect in order to safeguard life and health of a patient and others. The practice of nursing as a licensed practical nurse or licensed attendant is the performance of such duties as are required in the physical care of a patient or the carrying out of medical orders as prescribed by a licensed physician requiring an understanding of nursing but not requiring all the professional service or qualifications set forth in the definition of nursing as a licensed or registered nurse. H. 39 proposes that in any **proceeding to establish paternity** the court on motion of the defendant shall order the mother, her child and the defendant to submit to one or more blood grouping tests by a duly qualified physician to determine whether or not the defendant can be excluded as being the father of the child and the results of such tests may be received in evidence but only in cases where definite exclusion of the defendant is established. S. 83 proposes the creation of a committee to make a thorough investigation of the methods used by the **various state examining boards** and commissions concerned with the licensing of trades, occupations and professions with special reference to their conduct and grading of examinations and the furnishing of information with respect thereto to interested parties and make a full report of the result of such investigation to the General Assembly of the Commonwealth at the next regular meeting or special session of the General Assembly. S. 86 proposes the establishment of a board of trustees of the **State Fund for Inebriates** to study the problem of alcoholism, including methods and facilities available for the care, custody, detention, treatment, employment and rehabilitation of persons addicted to the intemperate use of spirituous or intoxicating liquors. S. 98 proposes that no hospital receiving any appropriation from the state shall give **any discount or rebate** to any hospital plan or medical service corporation, association or society for any service rendered or room furnished by it to any member of such corporation, association or society.

### South Carolina

**Bill Introduced.**—S. 45 proposes that before a **marriage license** may be issued each of the contracting parties must have filed with the probate judge a certificate signed by a duly licensed physician of the state certifying that within thirty days the physician examined such party and found him or her to be of sound mind and free from venereal disease.

### South Dakota

**Bill Introduced.**—H. 37 proposes regulations for the **licensing of osteopathic physicians.** The license would permit the holder to practice osteopathic medicine, surgery or obstetrics without limitation in any of their branches in the state.

### Texas

**Bills Introduced.**—S. 63 proposes the enactment of a basic science act which would require any person desiring to take an examination for a license to practice any branch of the healing art to first pass an **examination in the basic sciences** of anatomy, physiology, chemistry, bacteriology, pathology, and hygiene and public health. S. 78 proposes to include amphetamine, commonly known as "benzedrine," within the provisions of **the narcotic drug act.** S. 119 proposes to make it unlawful to sell **isonipecaine, barbital or benzedrine** except by drug stores licensed by the state board of pharmacy and upon written prescription of persons licensed in Texas to practice medicine and surgery, osteopathy, dentistry and veterinary medicine. S. 122 proposes the creation of a **state board of naturopathic examiners** and defines naturopathy as "that philosophy and system of the healing art embracing prevention, diagnosis, and the cure and treatment of human ills, diseases, traumas, deformities, and functions by the use of the several properties of air, light, heat, cold, water, mechanics, electricity, manipulation and psychology, together with the use of such substances, largely nutritional, of plant, animal or mineral origin as are naturally found in and required by the body, including drugs and major surgery."

### Utah

**Bills Introduced.**—H. 22, to amend the **narcotic drug act,** proposes to include "isonipecaine, amidone, isoamidone, and keto-bemidone" within the definition of "narcotic drugs." S. 135 proposes the enactment of a basic science law and states the **basic sciences** to be anatomy, physiology, pathology, bacteriology and chemistry.

### Vermont

**Bills Introduced.**—H. 70 proposes that a municipality may appropriate a sum of money to secure a **licensed physician or a registered nurse,** or both, and may join with adjacent municipalities in employing such physician or nurse, or both. H. 77 proposes an act to require the licensing, inspection and regulation of **hospitals and related institutions.** The licensing agency would be the hospital survey and construction commission and an advisory hospital licensing council would be appointed. "Hospital" is defined as a place devoted primarily to the maintenance and operation of facilities for the diagnosis, treatment or care for not less than twenty-four hours in any week of two or more unrelated individuals suffering from illness, disease, injury or deformity or a place devoted primarily to providing for not less than twenty-four hours in any week of obstetrical or other medical or nursing care for two or more unrelated individuals. The proposal is broad enough to include hospitals operated by the state, county, town, municipality or other political subdivision.

### Wisconsin

**Bills Introduced.**—A. 11 proposes regulations creating a **director of nursing education** and also proposes regulations for the licensing of practical nurses. A. 12 proposes the creation of a **state laboratory of hygiene.** This laboratory would be required to examine the following specimens without charge when submitted in proper containers by licensed physicians, veterinarians, health officers, and health commisisoners: material collected from patients afflicted with tuberculosis or from persons suspected of being afflicted with tuberculosis; blood from suspected typhoid cases and other enteric infections; swabs from persons suspected of having diphtheria, septic sore throat or other communicable diseases involving the upper respiratory tract and for the release from quarantine of persons who have been afflicted with these diseases; material from men or animals suspected of suffering from rabies, anthrax and glanders; examinations pertaining to industrial health hazards and such other examinations as may be necessary for the control and prevention of those diseases which cause a public problem.

## Coming Medical Meetings

Alaska Territorial Medical Association, Juneau, March 3-5. Dr. William P. Blanton, Box 2569, Juneau, Secretary.

American Academy of General Practice, Cincinnati, Netherlands Plaza Hotel, March 7-9. Mr. Mac F. Cahal, 231 W. 47th St., Kansas City, Mo., Executive Secretary.

American Association for Thoracic Surgery, New Orleans, March 29-31. Dr. Brian Blades, George Washington University Hospital, Washington, D. C., Secretary.

American College of Physicians, New York, March 28-April 1. Dr. George Morris Piersol, 4200 Pine St., Philadelphia 4, Secretary General.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, New York, Hotel Waldorf-Astoria, March 4. Dr. Norman N. Smith, 291 Whitney Ave., New Haven 11, Conn., Secretary.

Central Surgical Association, Cleveland, Hotel Cleveland, February 18-19. Dr. Walter G. Maddock, 250 E. Superior St., Chicago 11, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, Palmer House, March 1-4. Dr. H. Kenneth Scatliff, 30 N. Michigan Ave., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 14-17. Miss Thelma Webb, 1133 Medical Arts Bldg., Dallas, Executive Secretary.

Michigan Postgraduate Clinical Institute, Detroit, Book-Cadillac Hotel, March 23-25. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Mich., Secretary.

Missouri State Medical Association, Kansas City, March 27-30. Mr. T. R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Municipal Auditorium, March 7-10. Dr. W. D. Beacham, 1430 Tulane Ave., New Orleans, Secretary.

Postgradute Assembly in Endocrinology, Association for the Study of Internal Secretions, Oklahoma City, Feb. 21-26. Dr. Henry H. Turner, 1200 N. Walker St., Oklahoma City 3, Secretary

Southwest Allergy Forum, El Paso, Texas, Hotel Paso del Norte, April 4-5. Dr. O. E. Egbert, First National Bank Bldg., El Paso, Secretary.

# GOVERNMENT SERVICES

## ARMY

### COURSE IN BASIC SCIENCES FOR MEDICAL OFFICERS

Sixty-four of the nation's outstanding clinicians and medical investigators comprise the visiting faculty for the annual course in basic science recently opened at the Army Medical Research and Graduate School, Washington, D. C., which course is being pursued by a group of medical officers selected from Army installations throughout the country. The twenty-one week course is divided into three categories: (1) the utilization and metabolism by the total organism of the essential substances, water, electrolytes, carbohydrates, proteins and other accessory substances; (2) the subjects advanced by category 1 are elaborated on in category 2 in discussions concerning aberrations by the body in handling the substances when affected by such modifying agents as bacteria, heat and cold, heredity, rate of growth and development, the effect of radiation and drugs, etc., and (3) review of most of the basic subjects.

On opening the course, the welcoming address was made by Brigadier General George A. Armstrong, Deputy Surgeon General. Dr. Irvine H. Page of Cleveland spoke on "The Functions and Purposes of Basic Science Instruction," and Dr. Herbert M. Evans of the University of California on "Saving Your Own Life." Colonel Walter H. Moursund Jr. is director of the course. Commander Rufus L. Holt, Commandant, Army Medical Center, presided

### MEDICAL OFFICERS TEACH IN CIVILIAN SCHOOLS

Twenty-three medical corps officers, two medical service corps officers, two dental corps officers and one veterinary officer are now serving as part time instructors on the faculties of civilian medical schools. This is indicative, the Surgeon General says, of the close relationship growing between Army medicine and civilian institutions. General Bliss emphasized the mutual advantages to Army and civilian medicine derived from the interchange of medical knowledge which is accomplished by such a cooperative program. The medical officers who serve on the faculties of civilians institutions do so voluntarily without remuneration and, in many cases, on their own time. The work of these officers is not to be confused with the regular assignment of medical officers as professors of military science and tactics at universities where medical department R. O. T. C. units exist.

### CIVILIAN OFFICERS TO ATTEND COURSES

The following Medical Corps officers, in addition to those previously reported, have been selected to attend courses in civilian schools and hospitals:

| *Name* | *Institution* | *Course* |
|---|---|---|
| Simpson, John W., Lieut. Col. | Association for the Study of Internal Secretions, Oklahoma City, Feb. 21-26 | Endocrinology |
| Kowallek, Paul J, Jr., Capt. | Huron Road Hospital, East Cleveland, Ohio | General surgery |
| Marchese, Vincent, Capt. | Gouverneur Hospital, Gouverneur Slip, New York | Surgery |
| Pfeil, Edgar T., Jr., Capt. | University Hospital, Baltimore | Neurosurgery |
| Buck, Charles E., First Lieut. | Indiana University Medical Center, Indianapolis | Pathology |
| Creditor, Morton C., First Lieut. | Bellevue Hospital, New York | Internal medicine |
| Daniels, Roswell G., First Lieut. | Brooklyn Hospital, Brooklyn | Intern training |
| DeLuca, Frank R., First Lieut. | Harlem Hospital, New York | General surgery |
| Epstein, Franklin H., First Lieut. | Grace-New Haven Hospital, New Haven, Conn. | Medicine |
| Graves, Stuart, Jr., First Lieut. | St. Luke's Hospital, New York | Medicine |
| Goldwyn, Arthur, First Lieut.. | Morrisania City Hospital, The Bronx, N. Y. | Pediatrics |
| Koefoot, Robert E., First Lieut. | Charles T. Miller Hospital, St. Paul | Surgery |

### MONTHLY MEDICAL MEETING

At the Surgeon General's regular monthly medical meeting at Walter Reed Hospital, January 24, Dr. Owen H. Wangensteen, professor of surgery, University of Minnesota, Minneapolis, spoke on "Studies in the Etiology and Surgical Management of Peptic Ulcer," and Major Edwin J. Pulaski, M.C., Surgical Research Laboratory, Brooke Army Medical Center, Fort Sam Houston, Texas, on "Control of Peritoneal Infection in Gastro-Intestinal Tract Surgery."

## NAVY

### NEW REGULAR OFFICERS

The following doctors have been nominated for appointment to the Regular Navy Medical Corps, and on acceptaance they will report for their first active duty as indicated:

| Name | Residence | Institution |
|---|---|---|
| Skow, George D., Comdr. | Racine, Wis. | Naval Training Center, Great Lakes, Ill. |
| Ellis, Fred A., Lieut. Comdr. | Seattle | Naval Air Station, Seattle |
| Smith, Alexander C., Lieut. (jg) | Manhasset, N.Y. | Bellevue Hospital, New York |
| Warren, Robert, Lieut. (jg) | Oberlin, Ohio | Huron Road Hospital, East Cleveland, Ohio |

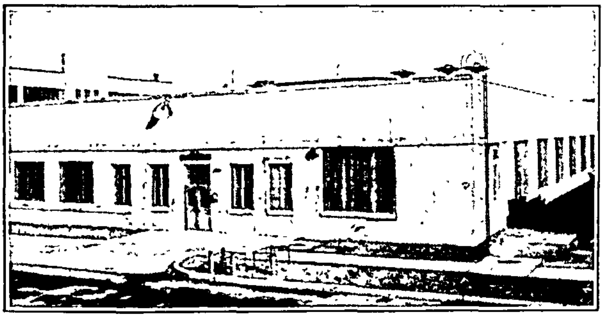
### MEETING OF CONSULTANTS

One of the most successful of the conferences of consultants to the Bureau of Medicine and Surgery was held at the Naval Medical Center, Bethesda, Md., January 28-29. Forty-three of the nation's civilian doctors, including the President and the President-Elect of the American Medical Association, attended the first joint meeting of the honorary and reserve consultants to the Medical Department of the Navy. A highlight of the meeting was an illustrated lecture by Commander J. M. Amberson, M.C., officer in charge of the Department of Tropical Medicine at the Naval Medical School, Bethesda, who reported on the Navy's recent medical mission in Africa for the study of tropical diseases and the collection of specimens for further study.

### COEDUCATIONAL HOSPITAL CORPS SCHOOL

The Surgeon General of the Navy, Rear Admiral Clifford A. Swanson, announces that the hospital corps schools at Great Lakes, Ill., and San Diego, Calif., henceforth will function as coeducational institutions for the first time. A selected group of twenty-eight Waves have been assigned to the schools and will pursue the same curriculum as the male hospital corpsmen, a twelve week course in the fundamentals of nursing, laboratory technic, ward management, materia medica, first aid and pharmacy and chemistry. During World War II, the Waves attended a separate training school to prepare for duty as hospital corpsmen. On completion of the courses, they will be assigned to Naval hospitals for further instruction and various duties in Medical Department hospitals.

## DEDICATE AERONAUTICAL MEDICAL EQUIPMENT LABORATORY



Navy Aeronautical Medical Equipment Laboratory.

This laboratory, originated in January 1942, is one of the newer laboratories of the Naval Air Experimental station and the only one of its kind in the Navy. Its facilities are comprised in two divisions: (1) the Human Engineering Division, which deals with the physiologic phases of aeronautic medicine, and (2) the Development, which deals with the study of scientific engineering problems relating to safety devices. The personnel consists now of 14 from the Navy and 44 civilians, the physical facilities include a clothing laboratory, an all-weather room, cold rooms, oxygen laboratory, physiology laboratories, altitude chambers, an ejection seat test tower, a screen room for electrical instrumentation and a dark room for vision studies. The Human Engineering Division, among other things, prepares recommendations from a physiologic point of view on technical investigations carried on in various laboratories, is responsible for physiologic testing of aviators' oxygen breathing equipment, clothing, safety and survival equipment, and for the indoctrination of personnel in the effects of low barometric pressures, extreme pressures, accelerations, use of oxygen-breathing equipment and electrically heated suits. The experience of various members of this division covers biochemistry, medical science, physics, physiology, instrumentation and piloting of aircraft.

At the dedication of the new laboratory, the principal address was given by Rear Admiral Clifford A. Swanson, the Surgeon General; other speakers were Rear Admiral F. W. Pennoyer Jr., Commander of the Naval Air Material Center; Commander P. E. Burr, Director of the Naval Air Experimental Station; Captain J. R. Poppen, Superintendent of the Aeronautical Equipment Laboratory; Rear Admiral B. Groesbeck, Assistant Chief, Bureau of Medicine and Surgery, and Colonel Robert E. Blount, M.C., U. S. Army, Office of the Air Surgeon.

## PERSONAL

The following lieutenants (jg) now under instruction in the Postgraduate Training Program have transferred to the Regular Navy: August P. Ciell of Roxborough, Pa.; James B. Flanagan of Tyler, Texas, and Hampton Hubbard of Charlotte, N. C.

# PUBLIC HEALTH SERVICE

## COURSES IN LABORATORY DIAGNOSIS OF INFLUENZA

In response to requests from state and local health department laboratories, the Influenza Information Center at Bethesda, Md., has arranged for refresher courses in procedures used in the laboratory diagnosis of influenza. The courses are open to experienced technicians from state and local health departments, and, while tuition free, no provision is made for paying the living expenses or travel costs of those who will take the training. These courses will vary in duration from one to three weeks and will be given at selected laboratories in New York, Maryland, Georgia, Pennsylvania, Illinois and California.

## NATIONAL SYMPOSIUM ON ANTIBIOTICS RESEARCH

The Second National Symposium on Recent Advances in Antibiotics Research, sponsored by the National Institutes of Health to promote research in antibiotics, will be held in Washington, D. C., in the auditorium of the Department of Agriculture, Independence Avenue between 12th and 14th Streets, S. W., April 11 and 12.

All persons interested are invited to attend and actively participate by the presentation of reports of their current investigations in this field. To those who contemplate presentation of materials, it is suggested that three copies of an abstract of not more than 250 words of the proposed report be sent in. Before inclusion on the program, each abstract must first be accepted by the Program Committee consisting of Dr. Henry Welch, chairman; Dr. Harry Eagle, Dr. Walsh McDermott and Dr. Leonard Karel. Only papers presenting original unpublished observations will be considered. It is planned to have all accepted papers published as a monograph or supplement by a scientific journal; the abstracts submitted in advance of the meeting should be written with this in mind.

Abstracts of papers should reach Dr. Leonard Karel, Executive Secretary, Antibiotics Study Section, Division of Research Grants and Fellowships, National Institutes of Health, Bethesda 14, Md., no later than March 10.

## FEDERAL AID FOR CANCER RESEARCH

National Cancer Institute grants of $508,527 to aid laboratory and clinical cancer research in nonfederal institutions were announced December 29 by the Federal Security Administrator. The awards had been approved by the Surgeon General of the U. S. Public Health Service after recommendations of the National Advisory Cancer Council which met in San Francisco to review the grant applications. Of the 50 grants approved, 18 are new and 32 are continuations. Fifteen states, the District of Columbia, and three foreign countries are represented. The projects to be aided by these grants include investigations of possible therapeutic agents; metabolism studies of cancer, using such technic as tracing by radioisotopes; physiologic and pathologic investigations of stomach cancer; studies on the production of cancer in experimental animals, with emphasis on the determination of possible causative agents, and comparative examinations of tissues and sera in normal and malignant states.

# AIR FORCE

## COURSE FOR AIR FORCE MEDICAL EXAMINERS

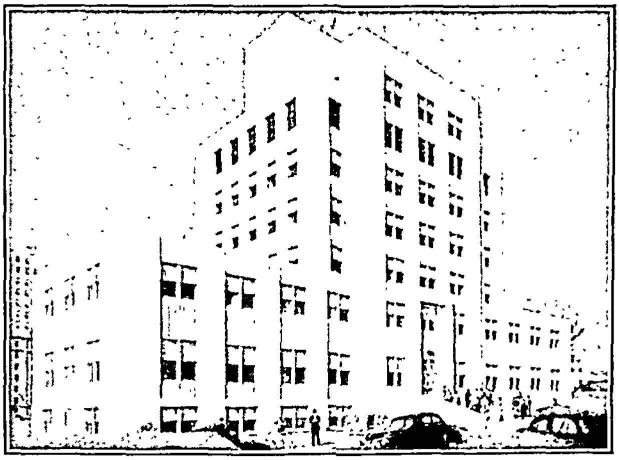
The Department of the Army announced January 25 that an eleven week course designed to qualify physicians as medical examiners for duty with the Air Force will begin March 28 at the School of Aviation Medicine, Randolph Field, Texas. The subjects to be taught include care of the flyer, air evacuation, neuropsychiatry, ophthalmology, surgery, otorhinolaryngology and preventive and global medicine. Those who graduate from the course will be designated aviation medical examiners. Applicants must be physically qualified in class III for flying as outlined in Army Regulation 40-110 and express a desire to serve with the Air Force. Officers now on active duty may apply through channels, and officers not now on active duty should submit applications to the Surgeon General, Department of the Army, Washington 25, D. C., not later than February 21.

# Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

## ALABAMA

**First Public Health Building Constructed with Federal Funds.**—The first public health center in the United States to be built with federal aid was dedicated and opened to the public in Birmingham January 27. The seven story structure was financed by about $300,000 in federal funds, to which were added the combined state-county and city funds of $600,000. The prinicipal dedicatory address was read for Dr. Leonard A. Scheele, Surgeon General of the U. S. Public Health Service, by his Deputy Surgeon General, Dr. W. Palmer Dearing. Other addresses were made by the present and immediate past governors of the state, Dr. Daniel G. Gill, state health officer, the Honorable Lister Hill, U. S. Senator, and Dr. George A. Denison, county health officer. The building will house offices of the Jefferson County Board of Health, Alabama state laboratories and voluntary agencies, such as the local branches of the tuberculosis association, the American Cancer Society, the National Foundation for Infantile Paralysis and Visiting Nurses Association. The City-County Health Department has been using emergency office space since the city hall burned in June 1944. Initial appropriations for the new building were made by the City Commission of Birmingham, the Jefferson County Commission and the State Building Commission during 1945. Ground was broken for the building in March 1947 before money was appropriated for the Hill-Burton Act. This is the first of sixty-three public health centers approved to date for federal aid under the national hospital program. Total federal funds of more than $107,000,000 have been allocated to hospital construction projects under this program for a total of 645 hospital and health facilities, according to the U. S. Public Health Service. It is the second building approved under the act in the entire country.



*Public Health Building, Birmingham.*

## ARIZONA

**Lectures in Medical Sciences.**—The staff of the Lois Grunow Memorial Clinic is presenting its third annual lecture series in medical sciences at the Lois Grunow Memorial Clinic, Phoenix, February 24-26.

**Pilot Mental Health Project.**—The Division of Mental Hygiene of the U. S. Public Health Service in cooperation with the Arizona State Department of Health has established a pilot project in Phoenix, Ariz., designed to develop and strengthen community resources for mental health. Personnel will devote most of their time to mental health training and consultation with staffs of well-baby and prenatal clinics, nursery and elementary schools, and health and welfare agencies in order to help them deal with emotionally disturbed persons in such a way as to prevent their reaching the point where they might need psychiatric treatment. The personnel from the U. S. Public Health Service assigned to this project comprise Dr. Walter M. White Jr., Huntington, W. Va., psychiatrist, a clinical psychologist, two psychiatric social workers and one mental health nurse.

## CALIFORNIA

**Dernham Cancer Fund.**—The recently established Laura and Henry and Irene B. Dernham Cancer Fund for research and education in cancer will be administered by the Dernham Trust Committee of the California Division of the American Cancer Society. A grant has been made to the University of California Medical School, Berkeley-San Francisco, for the study of the relationship between cancer growth and the host as studied with radioactive isotopes, under the direction of Kenneth W. Scott, Ph.D., department of radiology. Another grant has been made to Stanford University, San Francisco, to support an investigation of the effect of 4-aminopteroylglutamic acid and related compounds in the treatment of acute leukemia in children by Dr. Harold K. Faber, professor of pediatrics.

**Postgraduate Assembly for General Practitioners.**—The annual Postgraduate Assembly of the College of Medical Evangelists, Los Angeles, will be held February 25-March 1. In addition to professors of Western medical schools, papers will be presented by Drs. Frank H. Lahey, director, Lahey Clinic, Boston; Andrew Ivy, vice-president, University of Illinois, Chicago; Waldo E. Nelson, Temple University School of Medicine, Philadelphia, and Morris Fishbein, Editor, The Journal of the American Medical Association, Chicago. Dr. George T. Harding, newly elected president of the college, will discuss "The Relationship of Medicine to Religion." Doctors attending the scientific sessions will have a choice of eighty clinical presentations and general lectures during the three day meeting.

## COLORADO

**Damon Runyon Laboratory Established.**—The University of Colorado Medical Center announces the establishment of the Damon Runyon Laboratory of Chemical Embryology. The laboratory will be housed in a new cancer research wing to be constructed with funds made available by the National Cancer Institute of the U. S. Public Health Service and University of Colorado. A grant of $25,000, received in July from the Damon Runyon Cancer Fund, will be administered by a joint committee from the departments of biochemistry, obstetrics and gynecology and pediatrics. The director of the laboratory, who will begin his duties as associate professor of pediatrics (research) on July 1, is Heinz Herrmann, assistant professor of zoology at Yale University, New Haven.

## ILLINOIS

**Public Health Practices for Veterinarians.**—To give the veterinarian a better understanding of public health objectives and practices, the Illinois Department of Public Health is sponsoring an Institute on Public Health Practices for Veterinarians to be held in Springfield, March 21-23, to which all veterinarians are invited. The program has been designed to better acquaint veterinarians with the three basic public health practices, epidemiology, public health education and disease prevention and control. Subjects under discussion will include animal diseases transmissible to man, public health laboratory facilities, federal meat inspection, salmonellosis, food poisoning and infection, public health aspects of bovine mastitis, veterinary aspects of public health education and projects and plans for veterinary public health service in Illinois.

### Chicago

**Fund to Assist Students.**—The Patrick and Bertha Mooney Memorial Fund for the assistance of worthy students attending the University of Illinois College of Medicine has been established by Dr. Felix P. Mooney of Chicago, a graduate of the University of Illinois, as a memorial to his parents. The fund is to be used under the direction of Dean John B. Youmans.

**Dr. John Fulton to Give Billings Lecture.**—Dr. John F. Fulton, Sterling Professor of Physiology, Yale University School of Medicine, New Haven, will deliver the sixth Frank Billings Lecture of the Mary Holmes Nichols and Thomas Lewis Gilmer Foundation at a joint meeting of the Institute of Medicine of Chicago and the Society of Medical History of Chicago at the Palmer House, February 25, at 8 p. m., in commemoration of the William Osler centennial. His subject will be "Osler as a Humanist."

**Dr. Loosli to Head Preventive Medicine and Public Health.**—Dr. Clayton G. Loosli, associate professor of medicine and director of the Student Health Service of the University of Chicago, has been appointed to take charge of the Division of Preventive Medicine and Public Health in the School of Medicine. He also will direct the Influenza Detection Service established recently at the university by the U. S. Public Health Service. This service is concerned with the early detection of influenza and related respiratory diseases, their identification as to type and mass methods of treatment. Dr. Loosli was graduated at the University of Chicago Medical School in 1937. Dr. William G. Beadenkopf, assistant professor of medicine, has been named director of the Student Health Service.

**Reduced Amount of Dust in Air.**—Chicago's air was 8.7 per cent cleaner last year than in 1947, according to the annual report of the chief of the city's smoke inspection and abatement bureau. The city's monthly average fall of dust, 61.2 tons per square mile in 1947, was reduced in 1948 to 56.2 tons. The report showed a steady decline in the monthly dust fall over a six year period; in 1943 the average was 74.8 tons per square mile, and in 1948 it was 24.9 per cent lower. During March, the dirtiest month in 1948, the average fall from the twenty-three dustfall meters throughout the city was 75.1 tons. The Loop meter recorded the heaviest square mile fall last year, 164.2 tons. The steady decline in the total dust fall and the accompanying 50 per cent reduction of carbon content of dust indicates that smoke is contributing less to Chicago's air pollution. This is credited in part to an 8.8 per cent increase in railroad diesel locomotives during 1948. By the end of the year 45.7 per cent of all locomotive movements in the city had been dieselized. Another contributing factor was the council's adoption of an ordinance amendment giving the smoke bureau power to approve new and rebuilt fuel burning equipment.

## INDIANA

**Meeting of Study Group in Educational Campaign.**—The first meeting of a group within the Vanderburgh County Medical Society to develop a program of education on compulsory health insurance on the local level was held January 20. This group is the forerunner of a permanent committee which will be appointed to work out a detailed program. The committee will compile a library of source material, supply membership and all interested persons and groups with material for discussion and set up a speakers' bureau to get the facts before the people.

## LOUISIANA

**Dr. Heath Appointed Chairman of Psychiatry Department.**—Dr. Robert G. Heath, an instructor in neurology at Columbia University College of Physicians and Surgeons, New York, has been appointed chairman of the department of psychiatry and neurology at the Tulane University of Louisiana School of Medicine, New Orleans, effective February 1. Dr. Heath has been serving since 1947 as assistant attending neurologist at the Neurological Institute of New York and of the Vanderbilt Clinic. In 1942 he was chief resident of the institute and in 1943-1944 was demonstrator in neurology at Jefferson Medical College, Philadelphia. Dr. Heath received his medical degree from the University of Pittsburgh School of Medicine, 1938.

## MICHIGAN

**Graduate Degree in Ophthalmology.**—The Wayne University Graduate School, Detroit, beginning the second semester of this year, is offering major work leading to the degree master of science in ophthalmology. The course will be offered through the facilities of the College of Medicine.

**Personals.**—Dr. Howard Dittrick, Cleveland, was elected an honorary member of the Academy of Medicine of Cleveland December 29. He was editor of the academy's *Bulletin* for many years, an active member of committees and a recipient of its Distinguished Service Award in 1943. Dr. Dittrick is presently retiring as editorial director of the Cleveland Clinic.

## MINNESOTA

**Fellowship in Memory of Dr. Litzenberg.**—Friends, pupils and patients of the late Dr. Jennings C. Litzenberg, who was professor emeritus at the University of Minnesota Medical School, have asked the Minnesota Medical Foundation to set up a memorial fellowship. The foundation has agreed to act as trustee for the fund, which, if adequate, will be used to provide annually for the support of advanced training at the University of Minnesota, Minneapolis, or elsewhere, of especially promising physicians in obstetrics and gynecology or in basic science fields fundamental to maternal welfare. If the fund should be inadequate for this purpose, it will be used for some other appropriate subject to be determined by the trustees of the foundation.

## NEW JERSEY

**Rehabilitation Memorial Fund.**—Through the establishment of the Dr. Berthold S. Pollak Rehabilitation Memorial Fund, the Hudson County Tuberculosis League is offering rehabilitation services to county residents. Clients may include: (1) tuberculous persons discharged from hospitals; (2) tuberculous persons who were never hospitalized; (3) any person whose former illness or present handicap makes normal living difficult.

**Sixty Years of Service.**—A testimonial dinner was held February 10 by the board of directors of the Bayonne Hospital and Dispensary for Dr. Lucius F. Donohoe, medical director, on his completion of sixty years of practice in medicine. Dr. Donohoe is a graduate of New York University, 1889. He was elected to the staff in 1894 and became medical director in 1927. The hospital honored Dr. Donohoe in March 1944 on the occasion of the fiftieth anniversary of his appointment to the staff.

**Personals.**—Marguerite F. Hall, Ph.D., formerly associate professor of public health statistics, University of Michigan, Ann Arbor, has been appointed to direct the Bureau of Vital Statistics in the New Jersey State Department of Health. Dr. Carl E. Weigele of Trenton, who has been with the department since 1940, has been appointed head of the Bureau of Preventable Diseases.——A testimonial dinner honoring Dr. E. M. Zeh Hawkes of Newark was given October 29 by the medical staff of Presbyterian Hospital, from which Dr. Hawkes recently retired as medical director after twenty-one years of service. He was made medical director emeritus, a new post created by the board of trustees of the hospital. At the same time he received a citation from Union College, from which he graduated in 1887.——At the annual meeting of the American Public Welfare Association in Chicago, Dr. Ellen C. Potter, Trenton, deputy commissioner of welfare of New Jersey, received the W. S. Terry Jr. Memorial Award, "in recognition of her contribution to the field of public welfare administration, her unselfish devotion to the highest principles of social justice and her courageous battles on behalf of the underprivileged."

## NEW YORK

**Postgraduate Instruction.**—The Medical Society of the State of New York in cooperation with the New York State Department of Health has arranged a lecture on "Back Pain" by Dr. Samuel Kleinberg, New York, for the Geneva Academy of Medicine, meeting at the Belhurst Restaurant, Geneva, February 17 at 8:30 p. m. For the Madison County Medical Society a series of lectures will be given on Thursday evenings at the Hotel Oneida, in Oneida at 8:30 p. m. The schedule is as follows:

Feb. 17, Ferdinand J. Schoeneck, Syracuse, Sterility.
Feb. 24, William Woodin, Syracuse, Management of the Allergic Family.
March 3, Richard H. Lyons, Syracuse, Peripheral Vascular Disease.
March 10, Paul A. Bunn, Syracuse, Problems of Physical Diagnosis.
March 17, Leon G. Berman, Syracuse, Diagnosis and Treatment of the Acute Abdomen.
March 24, Edward M. Bridge, Buffalo, Recurrent Convulsions in Children.

**Seminar on Psychosomatic Problems.**—The Nassau Neuropsychiatric Society has planned a series of lectures for the Nassau County Medical Society on "Psychosomatic Problems in General Practice." Lectures will be given at 4 p. m. on Thursdays in the auditorium of the Nassau Hospital. The schedule is as follows:

March 10, Peter G. Denker, New York, Diagnosis and Therapy of Neurological Conditions in General Practice.
March 17, James L. McCartney, New York, Psychopathology as Found in Medicine and Surgery.
March 24, Charles E. Goshen, Hempstead, Psychopathology in Pediatrics.
John E. McGowan, New York, Mental Hygiene in the School Child.
March 31, Max Zuger, New York, What Psychoanalysis Has Contributed to the Understanding of Human Disease.
April 14, C. Milton Meeks, New York, Community Care and Commitment of the Mentally Ill.
Reginal R. Steen, New York, Care and Treatment in the State Hospital.
April 21, Round table discussion: Treatment of Nervous and Mental Diseases in Private Practice, James L. McCartney, Chairman, with H. Lawrence Sutton, Hempstead; Alexander E. Gold, New York, and Stanley T. Michael and John I. London, Brooklyn, participating.

### New York City

**Millions Left to Medical School.**—Ernest L. Woodward, former head of the Jell-O Company, who died April 16, 1948, left $2,198,571 to the University of Rochester School of Medicine for medical research and $250,000 to the Genesee Memorial Hospital in Batavia.

**Chandler Medals Awarded.**—The Charles Frederick Chandler medals, awarded periodically by Columbia University for outstanding scientific achievement, were presented January 25 to Henry C. Sherman, Sc.D., and Marston T.

Bogert, Sc.D. Dr. Sherman, Mitchell Professor Emeritus of chemistry, is widely known for his work in food and nutrition. Dr. Bogert is emeritus professor of organic chemistry.

**Association of Plumbers Establishes Blood Bank.**—A blood bank has been established at Memorial Hospital by the United Association of Plumbers Local 2, American Federation of Labor, to be supported by its 5,000 members for child victims of blood diseases. It will be named in honor of the Rev. William J. Kelley, chairman of the New York Labor Relations Board, who suggested that the blood bank be opened.

**New York Women Honored on Elizabeth Blackwell Anniversary.**—On the hundredth anniversary of the graduation of the first woman to receive a medical degree in the United States, Dr. Elizabeth Blackwell, five New York women physicians received the Elizabeth Blackwell citation for their contributions to medicine. Those receiving the awards were Drs. Lauretta Bender of the New York University College of Medicine, Connie Myers Guion of Cornell University Medical College, Anna Hubert of the New York Infirmary for Women and Children and May Wilson of Cornell University Medical College. Ceremonies were held at the New York Infirmary for Women and Children, which Miss Blackwell founded in 1853.

**Bureau of School Health.**—Under the recently organized Bureau of School Health, New York City doctors are supplying medical service to a million pupils in the elementary, parochial, junior high, vocational high and thirteen of the academic high schools in the city. The bureau, under the direction of Dr. Robert Culbert, expects to add 50 doctors to its present staff this year and to fill vacancies for 100 nurses. The elementary school medical service consists mainly of twenty minute routine examinations of newly admitted pupils with their parents present for consultation. In the first year of the program it is estimated that at least 50,000 pregraduation examinations will be given at the school and 25,000 by private doctors. The bureau also plans to gradually extend its services to all academic high schools.

**Appoint Director of Bureau of Nutrition.**—Dr. Norman Jolliffe, associate professor of clinical medicine, New York University College of Medicine, and lecturer on public health practices at Columbia University College of Physicians and Surgeons, has been appointed director of the Bureau of Nutrition of the City of New York Department of Health. Dr. Jolliffe, a graduate of the New York University College of Medicine, 1926, has served as head of the Department of Health's nutrition clinic in the Lower East Side Health Center since it was opened in 1945. He has served as a member of the Food and Nutrition Board of the National Research Council and has just finished editing a volume "Clinical Nutrition," sponsored by the council, which will be published this spring. He is also chairman of the New York Food and Nutrition Committee. The health department plans to open five other nutritional clinics within the next year.

**Symposium on Parasitic Infections.**—A symposium dealing with certain aspects of the biology, metabolism, immunity, diagnosis and treatment of the more common parasitic infections will be held at the New York Academy of Medicine under the auspices of the Section on Microbiology the evening of March 15 and afternoon and evening of March 16. The speakers and subjects to be discussed are as follows:

Paul Russell, New York, World Health Importance of Parasitic Diseases.
Clay G. Huff, Sc.D., Bethesda, Md., Significance of New Findings in Life Cycle of Malarial Parasites.
James T. Culbertson, Ph.D., Bethesda, Md., Immunological Mechanisms in Parasitic Infections.
John Bozicevich, M.A., Bethesda, Md., Immunological Diagnosis of Parasitic Diseases.
Norman R. Stoll, Sc.D., Princeton, N. J., Diagnosis of Intestinal Helminths and Protozoa.
William W. Frye, New Orleans, Studies on Growth and Metabolism of Endamoeba Hystolytica.
Theodor von Brand, Bethesda, Md., Physiology of the Blood Flagellates.
Quentin M. Geiman, Ph.D., Boston, Cultivation of Malarial Parasites.
Ralph W. McKee, Ph.D., Boston, Biochemistry and Metabolism of Malarial Parasites.
Ernest Bueding, Cleveland, Metabolism of Helminths.
Hamilton H. Anderson, San Francisco, Pharmacologic Evaluation and Clinical Application of Amebicides.
G. Robert Coatney, Ph.D., Bethesda, Md., World Status of Antimalarial Drugs.
Harold P. Brown, Ph.D., New York, Therapy of Filariasis and the More Common Intestinal Helminths.
Frederick J. Brady, Bethesda, Md., Chemotherapy of Schistosomiasis.

## OHIO

**Postgraduate Course on Diabetes.**—The Frank E. Bunts Educational Institute and Cleveland Clinic will present a continuation course for physicians entirely devoted to the diagnosis and management of diabetes and its complications on March 17-19. Drs. Henry T. Ricketts of Chicago, John S. L. Browne of Montreal and Hugh L. C. Wilkerson of the U. S. Public Health Service will be the out of town speakers. Dr. E. Perry McCullagh, Cleveland, is director of the course. In addition to the regular faculty of the institute several Cleveland physicians will give lectures. Inquiries regarding the program and registration may be addressed to the Director of Education, Frank E. Bunts Educational Institute, 2020 East Ninety-Third Street, Cleveland 6.

## PENNSYLVANIA

**Special Society Meeting.**—The March 12 meeting of the Pennsylvania Academy of Physical Medicine will be held at the Berkshire Hotel, Reading. An elaborate program has been planned for the afternoon and evening sessions, dinner and a Sunday tour of the countryside.

**Statewide Survey of Rheumatic Fever.**—The Medical Society of the State of Pennsylvania is conducting a statewide survey on the prevention of rheumatic fever. Each of the 10,750 physician members of the society has received registration blanks on which to report persons under 21 years of age with rheumatic fever; requests for 2,000 additional blanks have been received. Dr. Andrew B. Fuller, Pittsburgh, chairman of the society's Commission to Study Control of Rheumatic Fever, said that this is the first extensive and thorough registration made within the state. The survey is aimed at getting information on the number and location of cases to help in devising control measures. Rheumatic fever committees have been set up by the state medical society in the sixty county medical societies. Special meetings with little groups will be organized to acquaint the public with symptoms of the disease and safeguards to prevent it.

### Philadelphia

**Personal.**—Dr. George E. Farrar Jr., associate professor of medicine, Temple University School of Medicine, has been appointed medical director for Wyeth Incorporated, Philadelphia. He will continue his post at Temple University and maintain his connection as co-author of the U. S. Dispensatory.

**Dr. Chamberlain Awarded Medal.**—Dr. W. Edward Chamberlain, professor and head of the department of radiology at Temple University School of Medicine, has been awarded a gold medal, the highest honor of the Radiological Society of North America. It was presented at the society's annual banquet in San Francisco, December 9, for distinguished service to medicine. Dr. Chamberlain is a graduate of the University of California Medical School.

**Sigma Xi at Temple University.**—Temple University has been granted a charter to form a chapter of Sigma Xi, scientific research society of America. President of the chapter is Ralph Wichterman, Ph.D., associate professor of biology in the College of Liberal Arts. Sixty-five members of the faculty in the schools of medicine, dentistry, pharmacy, the college of liberal arts, Teachers College and the Research Institute of Temple University belong to the fraternity. James D. Page, Ph.D., associate professor and director of the psychological clinic, is secretary.

### Pittsburgh

**Course in Cardiovascular Diseases.**—The "Treatment of Decompensated Hearts" is the subject of the second of a series of postgraduate courses sponsored by the Allegheny County Medical Society's Graduate Education Committee. The course, to be given by Dr. Edward A. Brethauer Jr., includes six lectures presented in the Lecture Room at Elizabeth Steel Magee Hospital every Friday from 4 to 5 p. m., beginning January 21 and extending through February 25. The registration fee for the course is $10, which is payable to the Allegheny County Medical Society, 225 Jenkins Building, Pittsburgh. The number of registrants is not limited.

## RHODE ISLAND

**Meeting on Military Medicine.**—A joint meeting of the Rhode Island Medical Society and the Providence Medical Association was held at the Naval Air Station, Quonset, February 2. Captain Julius C. Early Jr., M.C., U.S.N., Washington, D. C., spoke on aviation medicine, and Captain Charles F. Behrens, M.C., U.S.N., Bethesda, Md., on "Medical Aspects of Atomic Warfare." A reception and dinner followed the meeting.

## GENERAL

**Orthopsychiatric Association Meeting.**—The 1949 annual meeting of the American Orthopsychiatric Association will be held at the Stevens Hotel, Chicago, April 4. This is an organization for the study of behavior and its disorders, particularly in children, and with emphasis on prevention of maladjustment as well as treatment. A registration fee will be charged for nonmembers.

**Research in Sex Problems.**—The Committee for Research in Problems of Sex of the National Research Council announces that requests for grants-in-aid during the fiscal period July 1, 1949 to June 30, 1950 will be received until March 15. Application blanks may be obtained from the Division of Medical Sciences, National Research Council, 2101 Constitution Avenue, Washington 25, D. C. Preliminary inquiries should be addressed to Dr. George W. Corner, Director of the Department of Embryology, Carnegie Institution of Washington, Wolfe and Madison Streets, Baltimore 5, chairman of the committee.

**Cartoon Booklet on Cancer Frauds.**—An eight-page cartoon booklet in four colors exposing quackery in the treatment of cancer will be distributed by the American Cancer Society through its sixty divisions in the United States during February. The booklet, aimed at an adult audience and entitled "Dr. Fraud Confesses," features a mythical Dr. Fraud, who administers quack cures until he discovers he is a victim of the disease and rushes to a real doctor with a confession. The booklet emphasizes that cancer can be cured if the patient is treated in time and that quacks delay effective treatment and are responsible for needless deaths.

**Foundation Prize in Obstetrics.**—The American Association of Obstetricians, Gynecologists and Abdominal Surgeons will present a Foundation Prize of $200 for the best 5,000 word manuscript from an intern, resident or graduate student in obstetrics, gynecology or abdominal surgery or from physicians who are actively practicing in the field or engaged in research. The award will be made at the annual meeting of the association, where the successful contestant must present his contribution. Three copies of all manuscripts must be in the hands of the secretary before June 1. For information address L. A. Calkins, M.D., secretary, University of Kansas Medical Center, Kansas City 3, Kan.

**Pharmacologic Reviews.**—Beginning with the first volume of 1949, a supplement entitled "Pharmacological Reviews" will be included with the last issue of each of the three volumes of the *Journal of Pharmacology and Experimental Therapeutics* published during the calendar year. Present plans call for supplements of about 160 pages each to appear with the April, August and December issues of the journal. The new supplement is edited by Dr. Louis Goodman, Salt Lake City. The first issue will contain articles on the anticholinesterases, drug-protein interactions, ganglionic and adrenergic blocking agents and salicylates. These supplements may be ordered separately from the journal at the rate of $2 each, or $6 a year, in advance, or may be included with the journal at an advance of $3 in the subscription price.

**Rheumatic Fever Mortality Rate Declining.**—The mortality rate of rheumatic fever has dropped 90 per cent in the United States since 1920, according to Dr. George M. Wheatley, vice president of the Metropolitan Life Insurance Company. The figure was based on mortality rates from rheumatic heart disease among industrial policy holders. The disease, he said, seems to be decreasing in severity and prevalence. The mortality decreased 22 per cent between 1920 and 1940 and has decreased 85 per cent in the seven years since then. He credits the large decrease in the last seven years to the use of antibiotic drugs in treating other ailments which lead to rheumatic heart conditions. Dr. Wheatley is chairman of the American Academy of Pediatrics' Committee on Rheumatic Fever and spoke at the recent annual meeting of the academy in Atlantic City.

**Fellowships in Child Guidance Clinic Psychiatry.**—The American Association of Psychiatric Clinics for Children offers fellowships for training in child guidance clinic psychiatry. These fellowships are made possible by the United States Public Health Service and sometimes by local funds. In addition, a few communities offer to finance the training of psychiatrists who will work for them on a contractual basis for a given period following their training. Most of the fellowships are for two years. The stipend is in the neighborhood of $3,000 for the first year, and around $3,600 for the second. The awarding of the fellowship for the second year depends on the quality of the first year's work. Prerequisites are graduation from an approved medical school, a general internship and two years of approved general psychiatry and personal qualifications essential for such work. For information write to Dr. A. Z. Barhash, executive assistant, The American Association of Psychiatric Clinics for Children, 1790 Broadway (Room 916), New York 19, N. Y.

**Farm Bureau Opposes Compulsory Health Insurance.**—The board of directors of the American Farm Bureau Federation on January 27 announced its opposition to compulsory health insurance programs such as those contemplated in the Murray Bill (S. 5). The board sent a telegram to the Senate Labor Committee asking that action be deferred on S. 5 until interested parties be given the opportunity to present their views. The text of the statement is in part: "We give all-out support to the extension of [medical and hospital services] on a voluntary basis, but we strongly oppose plans under which the federal government would embark on programs providing similar services on a compulsory basis. We favor adequate health services, accessible at all times to citizens through voluntary programs providing hospital and medical care, facilities to train more doctors and nurses, establishment of local public health units, and broad programs of health education.

"We believe that voluntary programs result in better medical service in greater volume than will be provided in any compulsory program and, at the same time, will do much to develop individual self-reliance and independence."

## CORRECTION

**Asthma and Coronary Occlusion.**—In a Query and Minor Note with this title in The Journal, Jan. 15, 1949, p. 191 in the nineteenth line of the paragraph numbered 4, it was stated that "one uses a tight tourniquet distal to the point of hypodermic." The word "distal" should have been "proximal."

**Seminar on Tumors of the Skin.**—On the joint Baltimore-Washington Seminar on Tumors of the Skin, sponsored by the Washington Society of Pathologists, Washington, D. C., February 5, the following corrections to the item that appeared in The Journal, January 1, page 43, should be made: Dr. Arthur C. Allen, Memorial Hospital, New York City, not Arthur A. Allen, Patterson, N. J., and Dr. Elson B. Helwig, Army Institute of Pathology, Washington, D. C., not of St. Louis, took part in the discussion.

# Marriages

James Talmadge Littlejohn of Jemison, Ala., to Miss Shirley Smith of Swannanoa, N. C., in Biltmore, N. C., December 18.

James Hollowell Manly Jr., Goldsboro, N. C., to Miss Dorothy Turner Hawthorne of Winchester, Va., December 22.

Merrill Frederick Nelson, Baltimore, to Miss Margaret McLeod Weskett of New Bern, N. C., December 29.

Lattie B. Painter Jr., Chattanooga, Tenn., to Miss Margaret Elizabeth Jack of Knoxville, December 4.

Albert Joseph Reinovsky, Washington, D. C., to Miss Willie Mae Hill of Cades, S. C., December 29.

Peter William Stone, Staten Island, N. Y., to Miss Dorothy Eleanor Harper in New York, December 27.

Silas David Molyneaux, Binghampton, N. Y., to Mrs. Kester Barr in Winnetka, Ill., November 6.

Benjamin E. Morgan, Birmingham, Ala., to Miss Jean Bailey of Rocky Mount, N. C., December 3.

Philip Burnard Potampa, Portland, Ore., to Miss Emmie Lee Cole of Florence, S. C., December 24.

Benjamin M. Stein, Hempstead, N. Y., to Miss Clair Wander of New York, December 31.

Frank P. Dwyer Jr., Renovo, Pa., to Miss Sarah Margaret Moffett, Ardmore, Pa., December 31.

Wallace Arnold Hull to Miss Joyce Burton, both of Indianola, Miss., December 17.

Paul E. Stange, Hoyleton, Ill., to Miss Astrid Zahn of Albany, Calif., in December.

Raymond C. Fergusson to Miss Dorothy Jackson, both of Seattle, November 26.

Ray O. Gillies Jr. to Miss Rachel Florence Koch, both of St. Louis, January 14.

Irving Puziss, Portland, Ore., to Miss Esther Cohen of Boston, December 5.

Nan Denholm to Mr. Thomas F. Wolcott, both of Flint, Mich., November 8.

# Deaths

**Ralph Bernstein,** Philadelphia; born in Columbia, Pa., April 12, 1877; University of Pennsylvania Department of Medicine, Philadelphia, 1903; Hahnemann Medical College and Hospital of Philadelphia, 1904; professor of dermatology at the Hahnemann Medical College and Hospital; fellow of the American College of Physicians and the American Academy of Dermatology and Syphilology; member of the American Academy of Political and Social Sciences and the American Association for the Advancement of Science; chief, skin section, and consulting dermatologist at the Broad Street Hospital; consulting dermatologist at the Women's Homeopathic Hospital, House of Detention for Juveniles and Shriners' Hospital for Crippled Children; consulting dermatologist at the West Jersey Hospital, Camden, Wilmington Homeopathic Hospital, Wilmington, Del., Crozier Hospital, Chester, Pa., Homeopathic Hospital, West Chester, Allentown (Pa.) State Hospital, Reading (Pa.) Homeopathic Hospital, Pottstown (Pa.) Homeopathic Hospital and Bancroft School in Haddonfield, N. J.; author of "Solidified Carbon-Dioxide," 1912, "Ultra Violet Rays in Modern Dermatology," 1918, and five editions of "Elementary Dermatology," the first in 1913 and the last in 1945; died November 19, aged 71, of coronary thrombosis.

**William Elisha Chenery** ⊕ Boston; born in Wiscasset, Me., June 14, 1864; Harvard Medical School, Boston, 1890; professor of laryngology emeritus at Tufts College Medical School; member of the executive committee and trustee of Boston University; fellow of the American Academy of Ophthalmology and Otolaryngology, American Laryngological, Rhinological and Otological Society and the American College of Surgeons; member of the American Association for the Advancement of Science, Massachusetts Society of Examining Physicians, National Geographic Society and others; specialist certified by the American Board of Otolaryngology; consultant in nose, throat and ear department, Evangeline Booth Maternity Hospital and Home, Brookline, Boston Dispensary and Children's Hospital; consultant, nose and throat department, Forsyth Dental Infirmary for Children; for many years on the staff of St. Elizabeth's Hospital; affiliated with the New England Baptist and New England Deaconess hospitals; died January 3, aged 84.

**James William Allbritain,** Kansas City, Mo.; University Medical College of Kansas City, 1896; member of the American Medical Association; on the staff of St. Mary's Hospital; died recently, in St. Luke's Hospital, aged 79, of myocardial infarct, coronary sclerosis and diabetes mellitus.

**Carleton Banks Austin** ⊕ Lordsburg, N. M.; Chicago College of Medicine and Surgery, 1915; served overseas during World War I; examining physician for the local draft board during World War II; for many years district surgeon for the Southern Pacific Railroad; died December 12, aged 57, of injuries received when struck by a truck as he was changing a tire on his car.

**Samuel Dunham Bader,** Columbia City, Ind.; Chicago Homeopathic Medical College, 1897; died December 12, aged 99, of injuries received in a fall.

**Clarence Truman Bahler** ⊕ Walnut Creek, Ohio; Western Reserve University School of Medicine, Cleveland, 1917; died October 23, aged 61, of coronary thrombosis.

**Jacob Nathaniel Bailey** ⊕ Paducah, Ky.; Hospital College of Medicine, Louisville, 1907; member of the Southeastern Surgical Congress; past president of the McCracken County Medical Society; affiliated with the Riverside and Illinois Central hospitals; died December 1, aged 65, of coronary occlusion.

**Gamaliel Wyatt Holmes Cheney,** Rome, Ga.; University of Virginia Department of Medicine, Charlottesville, 1919; member of the American Medical Association; affiliated with Floyd and McCall hospitals; died October 26, aged 63, of uremia and myocardial failure.

**Eva Hedwig Engel** ⊕ New York; Universität Bern Medizinische Fakultät, Switzerland, 1935; member of the American Psychiatric Association; died in the Harkness Pavilion October 20, aged 39, of heart failure.

**Edward P. Hand** ⊕ Holyoke, Mass.; Georgetown University School of Medicine, Washington, D. C., 1914; fellow of the American College of Surgeons; served during World War I; city physician for a three year term; affiliated with the Holyoke Hospital and Providence Hospital, where he died January 4, aged 59, of cerebral hemorrhage and chronic nephritis and hypertension.

**Luther Scott James,** Blackburn, Mo.; University of Missouri School of Medicine, Columbia, 1907; member of the American Medical Association; formerly assistant superintendent of the Missouri State School, Marshall; served during World War I; died November 29, aged 72, of coronary occlusion.

**William E. Jewett** ⊕ Adrian, Mich.; Starling Medical College, Columbus, 1897; fellow of the American College of Surgeons; died in Toledo, Ohio, December 3, aged 76, of acute coronary thrombosis and chronic nephritis.

**Jacob Arthur Johnson,** St. Paul; University of Minnesota Medical School, Minneapolis, 1928; member of the American Medical Association; affiliated with Midway Hospital and Mounds Park Hospital, where he died November 10, aged 54, of heart disease and cerebral hemorrhage.

**Aretaeus Kirk,** Philpot, Ky.; Hospital College of Medicine, Louisville, 1892; member of the American Medical Association; died October 18, aged 76, of hypertrophy of the prostate.

**Harry Judson Lipes,** Albany, N. Y.; Albany (N. Y.) Medical College, 1897; member of the American Medical Association; served in France during World War I; formerly on the faculty of his alma mater; on the staff of Albany Hospital, where he died November 25, aged 76, of carcinoma of the esophagus with metastases.

**John Spratt Mackrell** ⊕ Pittsburgh; University of Pittsburgh School of Medicine, 1909; served during World War I; affiliated with Belvedere General Hospital for many years; head of the school medical inspectors; died November 21, aged 64, of cerebral hemorrhage.

**Montrose Bovard Magoffin** ⊕ Mercer, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1912; served overseas during World War I; died in Jameson Memorial Hospital, New Castle, November 14, aged 63, of cerebral hemorrhage.

**John Wesley Pennington,** Howell, Ga. (licensed in Georgia in 1913); died in the Little Griffin Hospital in Valdosta, October 29, aged 71, of cirrhosis of the liver and cardiovascular disease.

**George Dimitre Popoff** ⊕ Canton, Ohio; Karl-Franzens-Universität Medizinische Fakultät, Graz, Austria, 1929; specialist certified by the American Board of Radiology; on the staff of Mercy Hospital; died in St. Louis recently, aged 50, of carcinoma of the lung with metastases.

**Harry Holman Rittenhouse** ⊕ Bridgeville, Pa.; University of Pittsburgh School of Medicine, 1911; died October 19, aged 63.

**Kennedy Furlong Rubert,** Owego, N. Y.; Dartmouth Medical School, Hanover, N. H., 1900; member of the American Medical Association; for many years county coroner; served during World War I; formerly school physician; died in Wilson Memorial Hospital, Johnson City, November 7, aged 79, of cerebral thrombosis.

**Daniel Edwin Sable,** Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1907; member of the American Medical Association and of the American Association of Industrial Physicians and Surgeons; chief of the city's department of public safety; served during World War I; died in Mercy Hospital, December 11, aged 64, of carcinoma of the sigmoid colon, with metastases to the liver.

**John Jay Terrall,** Augusta, Me.; Harvard Medical School, Boston, 1913; affiliated with the Augusta State Hospital; died November 25, aged 68, of interstitial nephritis.

**Henry Tetrev** ⊕ Riverside, Ill.; Chicago College of Medicine and Surgery, 1908; on the staff of St. Anthony's Hospital, Chicago; died November 7, aged 70, of carcinoma of the stomach.

**William Joseph Tierney,** New York; University of the City of New York Medical Department, New York, 1888; medical officer for the fire department for many years; died in the Lenox Hill Hospital November 23, aged 81.

**Isaac Raymond Vincent,** Mansfield, Pa.; Jefferson Medical College of Philadelphia, 1905; died in the Blossburg (Pa.) State Hospital November 20, aged 69, of intestinal obstruction and myocardial failure.

**Horace William Ward,** Winsted, Conn.; Baltimore Medical College, 1903; formerly health officer; died in the Litchfield County Hospital November 11, aged 69, of chronic nephritis, arteriosclerotic heart disease and essential hypertension.

**Alfred Weil,** New York; Universität Heidelberg Medizinische Fakultät, Baden, Germany, 1907; member of the American Medical Association and the American College of Allergists; died November 3, aged 64.

**John H. Weller** ⊕ State Farm, Mass.; College of Physicians and Surgeons, Baltimore, 1909; member of the New England Society of Psychiatry; medical director of Bridgewater State Hospital; died in City Hospital, Boston, November 19, aged 69, of heart disease.

### Joint Committee for the Representation of Consultants and Specialists

The National Health Service for the first time has brought consultants and specialists into the field of medical politics as much as general practitioners and so created the need for their organization on medicopolitical lines, which has long existed in the British Medical Association for general practitioners. The association has a Consultants' and Specialists' Committee, and the question has arisen whether this committee or the colleges and corporations, which are in the hands of consultants and specialists, should represent them in dealing with the government, which now controls the medical profession so much. Though the colleges and corporations certainly are the bodies which represent consultants and specialists, they are inexperienced in political negotiations, while the British Medical Association is greatly experienced. The rivalry between the British Medical Association and the other bodies, which might have been disastrous, has been averted by an agreement reached by a committee which represented both parties, in the following terms.

1. It is essential in the interests of consultants that a joint committee of the bodies concerned should be established to speak for consultants with one voice. 2. The terms of reference should be (*a*) to represent consultants and specialists in the impending negotiations with the government on matters arising out of the National Health Service; (*b*) to prepare and submit for consideration of its constituent bodies a scheme. 3. When a constituent body disagrees with a view of the joint committee, it shall be entitled to have its view represented to the government, provided that a conference has previously been held to produce agreement. 4. The following is to be the composition of the committee, with the number of representatives: Royal College of Physicians, 3; Royal College of Surgeons, 3; Royal College of Obstetricians and Gynecologists, 2; Royal College of Physicians of Edinburgh, 1; Royal College of Surgeons of Edinburgh, 1; Royal College of Physicians and Surgeons of Glasgow, 1, and Consultants' and Specialists' Committee established by the British Medical Association, 6.

### Aseptic Dispensing

The retail pharmacist who dispenses preparations containing penicillin must satisfy the inspectors of the Ministry of Health that he has the skill and equipment to do this without introducing bacterial contamination, in order to obtain a license for this work. The latest phase of this new development of pharmacy was shown to the public in an aseptic dispensary opened in London by Boots, the pharmacists. The work is done in a sterile air-conditioned room. The ampules are filled with sterile solutions in a nylon cage. The dispenser has only his gloved hands in this cage and must see what he is doing through a small mica window.

### Success of Immunization Against Diphtheria

In the first six months of 1948 more children were immunized against diphtheria by local authorities than in any half-year since the war. They numbered 347,000 and those under the age of 5 years 288,000. Before the war there was a yearly average of more than 50,000 cases of diphtheria and 2,900 deaths. Last year there were only a little over 10,000 cases and 244 deaths.

## ISRAEL

*(From Our Regular Correspondent)*

JERUSALEM, Jan. 4, 1949.

### Problems of Beleaguered Jerusalem

After the termination of the mandate on May 15, 1948, the continuation of the health services in Palestine remained entirely in the hands of the Jewish organizations, as all former government services in this respect were abruptly discontinued. The Jewish organizations succeeded in continuing the health services almost without change, although nobody could underestimate the difficulties prevailing at the time. A particular instance of the maintenance of the health services was given in Jerusalem during the time of its siege, from April to June 1948, when the city was completely severed from the rest of Israel.

*The Supply of Food to Besieged Jerusalem.*—It was strictly in keeping with the general attitude of the mandatory government that no stocks of food were laid in for Jerusalem. The Jewish organizations had food supplies available only for a very limited time, as Jerusalem's sole highway connecting it with the coast (Tel-Aviv) was cut by the Arabs from the beginning of April and could be passed only irregularly and at great peril.

As early as in March, a shortage of foodstuffs was felt in Jerusalem. The applications of Jewish representatives for the storage of supplies were not heeded by the mandatory government. The Jews established a rationing system of their own. From April 10, the distribution of food was undertaken according to plans, bread being the first commodity to be rationed. A daily quantity of 250 Gm. per person was given. This quantity was sufficient for families with small children, as children and adults received the same rations. During the month of May, an additional kilogram of bread weekly was given to every man doing hard work. The quality of the bread was under constant control and could be considered satisfactory. As from April, the distribution of food was divided as per districts, and undertaken against food coupons given out by the central food distributing authorities. Children and pregnant women received certain supplements, such as milk powder, eggs or butter. Table 1 shows the caloric values of the food distributed in Jerusalem from April 10 to June 10—the day when the first convoy with food again came through from Tel-Aviv.

TABLE 1.—*Values of Food Distributed in Jerusalem from April 10 to June 19*

| | April 10-30 | | May 1-31 | | June 1-19 | |
|---|---|---|---|---|---|---|
| Foodstuff | Children | Adults | Children | Adults | Children | Adults |
| Calories | 1,320 | 1,400 | 990 | 890 | 680 | 660 |
| Protein, Gm. | 37 | 39 | 38 | 34 | 29 | 29 |
| Animal protein, Gm. | 12 | 8 | 9 | 5 | 5 | 2 |
| Calcium, mg. | 350 | 250 | 290 | 140 | 250 | 180 |
| Iron, mg. | 5.6 | 6.6 | 5.5 | 5.3 | 4.2 | 4.1 |
| Vitamin A, I. U. | 390 | 285 | 265 | 145 | 50 | 44 |
| Vitamin $B_1$, mg. | 0.60 | 0.61 | 0.73 | 0.68 | 0.25 | 0.25 |
| Riboflavin, mg. | 0.46 | 0.28 | 0.51 | 0.25 | 0.30 | 0.18 |
| Nicotinic acid, mg. | 4.9 | 5.4 | 4.1 | 3.8 | 2.5 | 2.4 |
| Vitamin C, mg. | 5.7 | 5.7 | 1.6 | 0.8 | 0 | 0 |

Table 1 shows clearly how the food supplies for Jerusalem's population deteriorated in the course of those weeks. Bread rations, which had already been cut in May, were only 150 Gm. per day per person in June. Vegetables and fruit disappeared completely; meat, eggs and other food containing proteins were distributed in scantiest quantities only.

The children who received the same basic quantities as the adults were better provided for, but quantitatively only and not with respect to quality. This was particularly so with infants and young children, who were continuously given foodstuffs unsuitable for them, such as coconut fat, jam, dried peas and dried beans.

Table 2 shows the nutritional value of the food distributed per person (a family consisting of 4 persons—husband, wife and 2 children of 8 and 12 years, respectively). In comparison, the normal average standard values are indicated.

It goes without saying that a deterioration in the state of health during the months of the siege was inevitable. All types of avitaminoses were seen; toxicoses were particularly prevailing in infants and young children, and a decrease of 10 per cent of the body weight of every member of Jerusalem's Jewish community was the average. Gastric-intestinal diseases were relatively rare. It is conspicuous that amebiasis—a disease frequently seen in Jerusalem—practically disappeared, and not only the acute amebiasis, but also its secondary gastric-intestinal troubles. Strange to say, hypertensive persons showed an inclination toward improvement—and that in spite of the continuous excitement owing to shooting and bombardments day and night. No increase and no deterioration in hypertensive cases occurred.

At the end of June, with the arrival of the first food convoys from Tel-Aviv, the situation changed radically. Jerusalem's food supplies improved greatly from June 20 to June 30, and since then the normalization of supplying Jerusalem has further progressed. Today, everything necessary for the population's nutrition is available in adequate rations.

Table 2.—*Nutritional Value of Food Distributed Compared with Standard Values*

| Foodstuff | Standard Values Required | April 10-30 | May 1-31 | June 1-19 |
|---|---|---|---|---|
| Calories | 2,700 | 1,360 | 940 | 670 |
| Protein, Gm | 65 | 38 | 36 | 28 |
| Animal protein, Gm | 26 | 10 | 7 | 4 |
| Calcium, mg | 950 | 300 | 215 | 230 |
| Iron, mg | 12 | 6.1 | 5.4 | 4.1 |
| Vitamin A, I. U | 4,500 | 235 | 200 | 50 |
| Vitamin $B_1$, mg | 1.2 | 0.60 | 0.70 | 0.21 |
| Riboflavin, mg | 1.7 | 0.37 | 0.38 | 0.21 |
| Nicotinic acid, mg | 12 | 5.1 | 4.0 | 2.5 |
| Vitamin C, mg | 70 | 5.7 | 1.2 | 0 |

*Problems of Health Department.*—At a meeting of the Israel Medical Association in June 1948, Dr. Syman, medical director of the Health Department of Jerusalem, gave a review of the problems of the health department during the time of the Jerusalem siege.

Two major problems had to be solved: preventing epidemics and fighting starvation with all its consequences. The danger of epidemics had particularly increased, inasmuch as many houses had been destroyed and living conditions in various districts had deteriorated alarmingly. The simultaneous danger existed of typhoid and other infectious diseases prevalent in the Arab villages and suburbs surrounding Jerusalem. A vaccination campaign against typhoid as well as against cholera was inaugurated. The work was done by close collaboration of the respective medical experts, highly efficient teamwork fighting the fly plague, chlorinating the wells and controlling the sanitary systems. Another problem was the disposal of the refuse from the households. Transport possibilities were practically nonexistent. The refuse was put in sacks and loaded on small carts. A rather unexpected problem arose out of the fact that the various Jewish cemeteries could not be used any longer, as they were under fire by the Arabs. Sites were selected for provisional cemeteries, with a view to transferring the bodies later on to their permanent place of rest.

The blowing up of the pump station at Latrun—the main pumping work of the Jerusalem water line—made the water question acute. However, owing to the foresight of the Jewish organizations, all cisterns in Jewish Jerusalem had been thoroughly cleaned as early as March and April, and placed under the permanent control of expert bacteriologists. Thus, infections through contaminated water were indeed successfully avoided. The rationing of the supply of water was similar to that of food. The average daily quantity allotted each person was ten liters. This amount had to suffice for cleaning, cooking, washing and sanitary purposes. The distribution was carried out by means of coupons. Unfortunately, it happened only too often that people were hit by shrapnel splinters, etc., in the streets during the process of the water distribution.

However, this hardship also passed, and today Jerusalem is obtaining a normal water supply from the taps, through the new water installation laid by the Israel Government.

## PARIS

*(From Our Regular Correspondent)*

Dec. 20, 1948.

### Congress of Oto-Rhino-Laryngology

The forty-sixth congress of this organization took place Oct. 18-23, 1948, in the grand lecture hall of the Paris Faculty of Medicine under the presidency of Professor Sourdille (Strassburg). On the agenda was the surgical treatment of ozena, as reported by J. Ramadier and C. Eyries (Paris). The authors consider that the attempts at pericarotid sympathectomy yields inconsistent and transitory results. After discussing various technics for inserting under the mucosa a prosthesis of acrylic resin, they explained Eyries's method: detachment of the mucosa on the external and inferior walls of the nasal fossae, except at the level of insertion of the concha nasalis inferior; in the two cells, so constituted, insertion of a number of small acrylic sticks; in this way the external wall nearly comes in contact with the partition. Eyries obtains 90 per cent success; in 60 per cent of patients the nasal fossa becomes normal again, and in 30 per cent, a nonfetid mucopurulent rhinitis persists for a few months, but almost always yields to medical treatment. Pharyngolaryngeal ozena does not always constitute a contraindication; it regresses after the recovery from nasal ozena. J. Causse (Béziers) has operated on 42 patients with ozena with Eyries's technic and, since he has inserted acrylic resin under the fibromucosa of the partition, very good results has obtained in 55 per cent, good in 35 per cent and fair in 10 per cent.

### The Strasbourg Faculty of Medicine

In 1939 during the war, the faculty had to retire to Clermont-Ferrand as did the whole university, which was most affected by the German occupation. It has lost two scientists of international reputation, Professors Vles and P. Reis, of the biologic physics department, as well as a large number of students, either killed while fighting or deported. While the university came back to Strasbourg in 1945, the resumption of activity has been very hard, the institute of pharmacology and experimental medicine having been totally destroyed by bombing and the institutes of hygiene and bacteriology partially. Other institutes were closed and their installations ransacked by Nazis. The teaching was reorganized. In 1947-1948 the laboratories for medical biology, biologic chemistry and biologic physics were well equipped again with research material. Since then, the number of students has increased. Most of the medical and scientific societies resumed their activities in the course of the scholastic year 1945-1946.

### Anniversary of Anatoxin

Roux announced the discovery of anatoxin by Ramon twenty-five years ago. At one of the last meetings of the Academy of Medicine, Ramon recalled the properties of anatoxin. The application of this discovery permits the prophylaxis and the specific treatment of diphtheria, tetanus, botulism and exanthematous typhus. It has also a great economic value in protecting livestock against various diseases.

## THE LICENSURE OF THE D. P. DOCTOR

*Dear Sir:*—I should like to comment on your recent editorial ("The D.P. Doctor," The Journal, Nov. 13, 1948, p. 822).

Among the list of requirements of the various states for obtaining a medical license you state: "many of them demand fully accredited credentials which physicians from foreign countries frequently do not have." You fail to mention that these states, which constitute an extremely high percentage in this country, request graduation from an American medical school as the basis for a medical license and do not accept foreign graduates at all, regardless of the year of graduation. In another paragraph you state very correctly, "The medical schools of many of the foreign countries have been in a deplorable state since the beginning of the Nazi invasions." But what about these medical schools up to the year 1933? I graduated from the Medical School of Vienna in 1927, and saw hundreds of American doctors taking postgraduate courses from the same men who now are refused medical licenses in more than 50 per cent of the states, only because they are foreign graduates. It must be mentioned that these 50 per cent include most states of the South and Southwest, whereas states like New York, Illinois, Ohio, Massachusetts and California do not adhere to these restrictions.

I am a graduate of the Medical School of Vienna, 1927, as stated above; I was assistant to the famed pathologist, Professor Erdheim, and I have been a pathologist in Oklahoma for the past ten years. I have gained recognition among the members of the medical profession in Oklahoma and elsewhere as a pathologist; I have published several papers and presented papers before national societies. I have passed the examinations of the American Board of Pathology. I acquired a license to practice medicine in the State of New York in 1941 and became an American citizen in 1944. But I cannot obtain the license in Oklahoma and therefore cannot be a member of the American Medical Association, cannot belong to the county medical society, cannot be certified by the Board or belong to the College of Pathologists or to the American Society of Clinical Pathologists. How can you consider that a fair treatment? Did I not graduate at a time when medical education in Europe was equal to that in the United States?

I deeply appreciate the opportunity given me in the United States in general, and in the state of Oklahoma in particular, to rebuild my professional life in a way impossible in most other countries. I have shown and will continue to show my gratitude by contributions to medicine in my field to the best of my ability. But I do feel that after ten years one should become a full-fledged member of the medical profession, just as after five years one becomes an American citizen with all rights and duties. I do not feel, as you do, that the "state medical licensing boards have considered the cases of D.P. physicians with the utmost sympathy and liberality."

What can be done to change the regulations of the various states regarding the licensing of foreign graduates? Could not the year of graduation and the length of residence in the United States be made an issue in this problem? Refugee physicians have been urged to locate in the central parts of the states rather than on the East or West coast. At the same time, this is made impossible by the restrictions imposed on them in those central states.

Leo Lowbeer, M.D.,
Pathologist, Tulsa, Okla.

## TREATMENT OF ACUTE RENAL INSUFFICIENCY

*To the Editor:*—Many measures are currently being advocated for the treatment of acute renal insufficiency. The mechanisms of the renal failure include the various causes of "lower nephron nephrosis" (Lucke, B.: *Mil. Surgeon* **99**: 371, 1946), mercury poisoning, "reflex anurias," etc. The methods of treatment include peritoneal lavage, various artificial kidneys, perfusion of isolated intestinal loops, etc. The most recent method is that of exchange transfusions (J. A. M. A. **138**: 902, 1948). Recovery of the patient is believed due to the replacement therapy; unfortunate results are ascribed to inadequate continuation or repetition of the therapy.

Few of the proponents of each specific mode of treatment stress the spontaneous resolution of the anurias. Furthermore, there is no means at present of accelerating the recovery of the injured kidney segment. Any measure available at present may at best tide the patient along to the point of spontaneous recovery.

At the Mount Sinai Hospital, New York, Drs. H. E. Leiter, I. G. Kroop, A. Hyman and I investigated a group of patients who were referred to the hospital for treatment with the Kolff artificial kidney. It was soon found that despite the urgent transfer to the hospital, mechanical dialysis was not necessary. Under conservative management, diuresis and cure occurred spontaneously. The greatest difficulty in medical control of these patients was the circulatory embarrassment due to the overzealous administration of fluids by vein by anxious physicians who were attempting to "flush" the kidneys. Thus, a 20 year man with acute "toxic anuria" had been given 10,000 cc. of sodium chloride, sodium sulfate and glucose solutions by vein in forty-eight hours, and died a few hours after admission in acute pulmonary edema. Experiences such as this open to question the validity of modes of therapy which focus on the administration of large volumes of fluid intravenously to dilute "toxins" or "open the kidneys" (Hoffman, W. S., and Marshall, D.: *Proc. Central Soc. Clin. Research,* 1948, to be published).

We have found the following principles effective in the management of acute renal insufficiency. Simplicity and ease of execution are combined with the least drain on the patient. Fluids are administered almost exclusively by mouth to replace insensible loss plus other eliminated fluid (1,000 cc. plus fluid in vomitus, stool and urine). Fluids by vein are kept to a minimum. Since blood urea nitrogen is the barometer for the degree of uremia, a protein-free diet is given. Particular attention is directed at the maintenance of electrolyte balance. Daily serum chloride and carbon dioxide contents are determined and sodium chloride and sodium bicarbonate are given by mouth to combat acidosis. Subcutaneous administration of solutions is resorted to if the patient cannot tolerate food by mouth. Rarely is any other fluid than blood given by vein.

On this program, despite a persistent oliguria or anuria, the patient may remain comfortable, free of edema and heart strain, despite a progressive rise in blood urea nitrogen (Fishman, A. P., and others, *Am. J. Med.,* to be published; Leiter, H. E., and others, *J. Urol.,* to be published; Fishman, A. P., and others, *New York State J. Med.* **48**: 2393, 1948; Kroop, I. G., and others, *J. Mt. Sinai Hosp.,* to be published). If it then becomes necessary to resort to artificial dialysis, the patient is in adequate physical condition to withstand the demands of the procedure.

Each method of intervention in the management of acute renal insufficiency has intrinsic hazards. The potential dangers of peritoneal lavage, artificial kidney, etc., as well as their limitations, are available in the literature. The hazards of homologous serum jaundice and even hemoglobinuric nephrosis seem obvious in exsanguination technics. Furthermore, the depression of blood urea nitrogen by removal of the circulating blood volume and replacement can only effect an extremely transient depression of blood urea and "toxic products." Its effects are most probably even more transient than any of the advocated methods of dialysis.

Since maximum benefit from conservative therapy may be anticipated up to the eighth to tenth day of anuria, mechanical intervention should, if possible, be deferred to that time. The majority of patients treated as outlined will require no further therapy; those who do require additional treatment will be better prepared to withstand it.

Finally, I believe that the large number of reported cures, despite the use of diametrically opposed methods of treatment, is excellent evidence for the high frequency of spontaneous cures, often despite the method used, rather than because of it.

Alfred P. Fishman, M.D.,
Dazian Foundation Research Fellow,
Michael Reese Hospital, Chicago.

## DETECTION OF DIABETES

*To the Editor:*—Dr. Joslin states in his excellent article on diabetes therapy (The Journal, January 1, p. 1) that for every known diabetic person there is an unknown diabetic. With this I think there is little disagreement. He makes the very interesting suggestion that, in order to uncover these unknown persons with diabetes, the physician and the diabetic patient do urinalyses on the relatives of known diabetics, especially the fat ones. This is a good plan, but I would go a step further. Why does not everyone, not just diabetics but everyone, check his own urine for sugar—say once each week?

It occurred to me some time ago, after testing a urine sample for sugar with the "clinitest," how simple a procedure this is—just a matter of adding a tablet to a few drops of urine and water. A child could be taught how to perform this test by the time he is 6 years old with the ease he is taught to brush his teeth. I suggest that an educational program be instituted to put over the idea that everyone in the country check his own urine once a week. It is less trouble than brushing one's teeth, and most of us have been taught to do this twice daily. Of course, they would be told to report to their physician in the event of a positive test. Most of the unknown diabetic persons could be discovered, and many of them could be cured of their disease. Many workers in this field feel that if one could catch a diabetic person within the first month or two, and before he has symptoms, and start him on insulin immediately, the pathologic changes which have occurred in the pancreas may be reversed. There is considerable experimental evidence to support this. Lukens (*Yale J. Biol. & Med.* 16: 301, 1944) obtained data showing that the blood glucose level may be the factor that determines the progress of hydropic degeneration of the islet cells. This change is one of the early abnormalities noted and is reversible with adequate doses of insulin in one to four months. In animals, artificially produced diabetes can be cured when treated in this stage of the disease, and the same is probably true in human beings.

It is estimated that 50,000 persons still die of diabetes in this country annually. If even a fraction of that number could be saved by this method, it would be well worth it.

As I suggested, this plan would have to be put over on a nationwide scale as a campaign to eradicate diabetes mortality. It is even possible that we would see most persons eventually cured of the disease. Other health campaigns in this country have been very successful. The cancer and the tuberculosis campaigns, especially, have probably saved countless lives. I see no reason why it would not be equally successful as regards diabetes.

R. W. Brown, M.D., Ogden, Utah.

## LUNG CANCER IN CHROMATE WORKERS

*To the Editor:*—Since rapidly rising death rates for lung cancer in recent years have brought medical attention to sharp focus on this disease, great interest attaches to statements of Machle and Gregorius (*Pub. Health Rep.* 63: 114, 1948) that chromate workers exhibit rates ten to seventy times those normally to be expected. The recent editorial (The Journal, 138: 823, 1948) gave added importance to their statement. The rates they found among chromate workers are not strikingly different, however, from those prevailing generally among similar population segments of Chicago's industrial districts (where no chromate-producing plants are located).

White men 50 to 69 years of age living in Chicago's Loop district have a lung cancer (No. 47 International List of Causes of Death) death rate of 16.0 per 10,000 man-years of exposure for the years 1944, 1945 and 1946 (based on 1940 population figures). This is above the average rate of 12 per 10,000 man-years found by Machle and Gregorius in two of their chromate plants. It is true that much higher rates were found in two other plants, a difference for which they offer no explanation. Even in a much larger segment of Chicago's dirtier district (community areas 8, 26-28, 31-39, 59-61) white men 50 to 59 years were found to have a lung cancer death rate of 11.3 per 10,000 man-years of exposure, while in the cleanest sections of the city men of these age groups had a rate of 7.9.

It is unfortunate that Machle and Gregorius should not have selected a more appropriate control group before publishing their statements that chromate workers had lung cancer rates ten to seventy times higher than the "controls." Their control group consisted of oil refinery workers whose places of work were not specified but often are located in semirural districts. Moreover, their control statistics dated back to 1933-1938, when lung cancer rates generally were still much lower than today.

Over half of their chromate workers were located in the dirty Jersey City–Newark industrial area, and the next largest group in Baltimore. Obviously, therefore, they should have selected a control group from industrial areas with equal degrees of air pollution. Had they done so, their conclusions would have been considerably more tempered.

In view of the high lung cancer rates we have shown (Mills, C. A., and Mills-Porter, M.: Health Costs of Urban Air Pollution, *Occup. Med.*, in press) to be generally prevailing among white men of dirty industrial districts, it seems wiser to read with considerable reservation their statement that ". . . the ratios of deaths and mortality rates for cancer of the lung are so consistently high as to leave no doubt as to the relationship between exposure to chromate and the occurrence of cancer of the respiratory system." They also found high pneumonia and tuberculosis rates among chromate workers, quite as we showed for Chicago's dirty districts where lung cancer rates were highest.

It would not seem justified to ascribe to chromate exposure any specific place in lung cancer causation until the role of air pollution generally prevailing in such districts has been properly evaluated.

Clarence A. Mills, M.D.,
Cincinnati, Ohio.

# Medical Examinations and Licensure

## COMING EXAMINATIONS AND MEETINGS

### NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers, Feb., June and Sept. 1949. *Part II.* April 1949. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2, Pa.

### EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology, Inc.: *Written.* July 15. Various locations. Final date for filing application is April 15. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Avenue, New York 27.

American Board of Dermatology and Syphilology: *Written.* Various Centers, Feb. 17. *Oral.* New York City, April 1-3. Sec., Dr. George M. Lewis, 66 East 66th Street, New York 21.

American Board of Internal Medicine: New York City, March 23-25. Philadelphia, June 1-3. *Written.* Oct. 17, 1949. Final date for filing application is May 1. Asst. Sec-Treas., Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* Chicago, June 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

American Board of Obstetrics and Gynecology, Inc.: *Oral.* Chicago, May 8-14. Final date for filing application is April 1. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh 6.

American Board of Ophthalmology: *Oral.* San Francisco, March 21-24; New York, June 11-15; St. Louis, Oct. 15-19; Boston, Dec. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopedic Surgery: *Part I.* Various Centers, April and May. Sec., Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14.

American Board of Otolaryngology: New York, May 11-14; Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

American Board of Pathology: Boston, April. Final date for filing application is March 1. Sec., Dr. Robert A. Moore, 507 S. Euclid Ave., St. Louis 10, Mo.

American Board of Pediatrics: *Oral.* St. Louis, Feb. 18-20. Baltimore, May 7-9. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Rd., Rosemont, Pa.

American Board of Physical Medicine: Atlantic City, June 4-5. Final date for filing application is March 15. Sec., Dr. R. L. Bennett, 30 N. Michigan Blvd., Chicago.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the home town of applicants. Sec., Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Psychiatry and Neurology: *Oral.* May. Final date for filing application is Feb. 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, March 1949. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: Feb. 1950. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18, Minn.

### BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 28-30. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

Alaska:* Juneau, March 1. Sec.-Treas., Dr. W. M. Whitehead, Box 140, Juneau.

Arkansas:* Little Rock, June 9-10. Sec., Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 9-10. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

California: *Examination,* Los Angeles, Feb. 28-March 3. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento.

Connecticut:* Hartford, March 8-9. Secretary to the Board, Dr. Creighton Barker, 258 Church Street, New Haven.

District of Columbia:* *Reciprocity,* Washington, March 14. Sec., Dr. George C. Ruhland, 4130 Municipal Building, Washington.

Florida:* *Examination,* Jacksonville, June 26-28. Sec., Dr. Frank D. Gray, 12 N. Rosalind Ave., Orlando.

Georgia: *Examination.* June, Atlanta and Augusta. *Reciprocity.* Atlanta, June. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

Guam: *Endorsement.* Agana, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam, % F.P.O. San Francisco, Calif.

Indiana: *Examination.* Indianapolis, June. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, 416 K. of P. Bldg., Indianapolis.

Iowa: *Examination.* Iowa City, June 13-15. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kentucky: *Examination.* Louisville, June 15-17. Sec., Dr. Bruce Underwood, 620 S. 3rd St., Louisville 2.

Maine: Portland, March 8-9. Sec., Dr. Adam P. Leighton, 192 State Street, Portland.

Maryland: *Examination,* Baltimore, June 21-24. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore.

Massachusetts: *Examination.* Boston, March 8-11. Sec., Dr. George L. Schadt, 413 E. State House, Boston.

Mississippi: Jackson, June. Asst. Sec., Dr. R. N. Whitfield, State Board of Health, Jackson.

Montana: Helena, April 4-6. Sec., Dr. O. G. Klein, First National Bank Building, Helena.

Nebraska:* *Examination.* Omaha, June. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Building, Lincoln 9.

Nevada: Carson City, May 2. Sec., Dr. G. H. Ross, 112 N. Curry Street, Carson City.

New Hampshire: Concord, March 10. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

New Jersey: *Examination.* Trenton, June 21-24. Sec., Dr. E. H. Hallinger, 28 West State Street, Trenton 8.

New Mexico: Santa Fe, April 11-12. Sec., Dr. V. E. Berchtold, 141 Palace Ave., Santa Fe.

North Carolina: *Endorsement.* Pinehurst, May 9. *Examination.* June 23-25. Sec., Dr. Ivan Procter, 226 Hillsboro St., Raleigh.

Ohio: *Endorsement.* Columbus, April 5. *Written.* Columbus, June. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Puerto Rico: *Examination.* Santurce, March 1. Sec., Mr. Luis Cueto Coll, Box 3717, Santurce.

South Carolina: Columbia, June 27-29. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

Texas: *Examination.* Austin, June 16-18. Sec., Dr. M. H. Crabb, 209 Medical Arts Bldg., Fort Worth 2.

Utah: *Examination.* Salt Lake City, July. Sec., Dept. of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

Virginia: *Examination.* Richmond, June 17-18. *Reciprocity.* Richmond, June 16. Dr. K. D. Graves, 631 First St., S.W., Roanoke.

### BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: Juneau, Feb. 21-26. Sec.-Treas., Dr. C. Earl Albrecht, Box 1931, Juneau.

Arizona: *Examination.* Tucson, March 15. Sec., Dr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

Colorado: *Examination.* Denver, Mar. 2-3. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

District of Columbia: *Examination.* Washington, April 18-19. Sec., Dr. George C. Ruhland, 4130 Municipal Bldg., East, Washington.

Florida: *Examination.* Gainesville, June 11. Sec., Mr. M. W. Emmel, University of Florida, Gainesville.

Minnesota: *Examination.* April, June and Oct. Sec.-Treas., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

Oklahoma: Spring of 1949. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: Portland, March 5 and June 18. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

South Dakota: Vermillion, June 3-4. Dr. G. M. Evans, 310 E. 15th St., Yankton.

Tennessee: Memphis, March 21-22. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

Wisconsin: Madison, April 2. Milwaukee, June 4. Sec., Prof. W. H. Barber, Ripon College, Ripon.

# Bureau of Legal Medicine and Legislation

## MEDICOLEGAL ABSTRACTS

**Malpractice: Dentist's Failure to Remove Broken Drill from Jaw; Statute of Limitations.**—The plaintiff sued for damages alleged to have been due to the negligence of the defendant dentist. From a judgment for the plaintiff the defendant appealed to the Supreme Court of Arizona.

The defendant assigned as error the trial court's denial of his motion for an instructed verdict as well as its refusal to grant his motion for a new trial. The basis for each motion was that there was no evidence, or at least that the evidence was wholly insufficient, to sustain the judgment in that the plaintiff had not established either negligence or proximate cause, nor had fraud or concealment been proved so as to toll the statute of limitations.

In 1935 the plaintiff consulted the defendant, a regularly licensed and practicing dentist, relative to the removal of two embedded wisdom teeth. After roentgenograms were taken by the defendant, the lower left third molar (wisdom tooth) was removed in an operation which lasted about two hours and thirty-five minutes and which involved cutting this tooth in two twice with a drill to facilitate its removal. The plaintiff was unaware of any untoward incident in connection with the operation, but he did testify that there seemed to be considerable trouble in effecting the tooth's removal and that about twenty-nine days elapsed before the gum healed. Though no roentgenograms were taken by the defendant following the removal of the teeth, it was established by other doctors who testified that, unless there was an apparent reason for doing so, standard practice would not require it. The plaintiff also testified that, following the operations, a little swelling and soreness was present now and then, at intervals of from four to six months, in his lower left jaw. Thinking, as the defendant had suggested after the operation, that a chipped bone was causing the trouble, the plaintiff went back to the defendant in the year 1938 or 1939. The defendant then made a roentgen examination of all of his teeth and jaw and gave the plaintiff the roentgenograms, telling him that there was nothing there that should give him any trouble. From that time until December 1941 or January 1942, the plaintiff's health gradually became impaired. He suffered from rheumatism, and the hearing in his left ear became affected. In all he lost about three hundred days from his usual work. He visited numerous physicians to discover the nature of his trouble, and they all informed him that there was an infection some place in his body but they could not determine where it was. Finally, in December 1941 or January 1942, after his gums had swollen up and abscessed and the abscess had broken, the plaintiff went to a Dr. Knower, who proceeded to x-ray the afflicted area where the left lower wisdom tooth had previously been removed. It was then, and not until then, that the plaintiff had learned that there was a piece of metal embedded in the jaw bone in that area, and that another small metallic particle lay externally to the bone opposite the second molar tooth region. Dr. Knower advised the plaintiff that the removal of these foreign bodies was a job for a specialist and recommended Dr. Borah of Phoenix. This advice was followed and in January 1942 Dr. Borah skilfully removed the object embedded in the jaw bone. The plaintiff, in answer to a question as to what procedure Dr. Borah followed, stated that the doctor first made a roentgen examination of the jaw to determine where he wanted to work, that thereafter the doctor would work a little while and then take a roentgenogram again, taking in all about a dozen roentgenograms, that "he removed that drill and laid it right on the table right there in front of me," that the witness saw him take it out and that this metallic object (which was admitted in evidence) had been in his possession ever since. The object removed was described as being 4 mm. in length and 1 mm. in width, slightly narrow in the central portion and slightly expanded at each end.

The gravamen of plaintiff's cause of action is negligence by the defendant in the extraction of the lower left impacted wisdom tooth, and the defendant's subsequent concealment of the true condition of the jaw bone and gum in that immediate area. The defendant knew, said the court, or by the exercise of reasonable diligence should have known, that the instruments used by him had broken off during the operation, and the failure to recognize that this had happened is regarded as malpractice. In such circumstances good practice would have dictated the taking of another roentgenogram, which would have disclosed the true condition and by an immediate correction thereof all of the subsequent difficulties encountered by the plaintiff would have been prevented. Dr. Borah testified that the object in question would have been readily observable in a roentgenogram of the area. In response to this question propounded by the trial court, ". . . if a piece of metal is left in the jaw of a patient after the removal of a tooth, does such a practice conform with the standard, the ordinary standard of the practice of dentists in the community in which you practice?" Dr. Borah gave an unequivocal answer, "No." Thus, said the court, there was supplied affirmative evidence of a violation of standards of medical practice essential to the sustaining of a verdict in the malpractice case.

In addition to establishing the defendant's negligence, said the court, it was also incumbent on the plaintiff to prove that this negligence was the proximate cause of his injury. Dr. Borah, who is both a medical doctor and a dentist, stated that if a foreign body is acting as an irritant and there is some disturbance from which the patient could be getting absorption, this could be a possible source of infection. He stated that he did not believe that the presence of a foreign body such as that involved in this case could cause rheumatism, but it might contribute to it. It would seem to be more than a mere coincidence, the court continued, that all of the plaintiff's physical ailments heretofore set forth occurred subsequent to the extraction of his wisdom teeth by the defendant and that within five or six months after the small metallic object had been removed he began to recover; he slept better, the soreness left his joints and his impaired hearing cleared up and bothered him no longer. At the time of the trial the plaintiff had completely recovered from the effects of his illness. We are, said the court, of the opinion that the evidence was amply sufficient to justify the trial court in submitting the case to the jury. We also hold that the evidence fully sustained the implied finding of the jury that it was through the negligence of the defendant that these two foreign metallic substances became embedded and were left in plaintiff's left jaw and that this negligence was the proximate cause of the injuries which plaintiff sustained.

Finally, continued the Supreme Court, we consider the question presented whether or not this action was barred by the statute of limitations. It was decided on a prior appeal of this case that fraud and concealment are sufficient to toll the running of the statute of limitations until the date of discovery of the fraudulent conduct. Do these facts fit such a rule, asked the supreme court. In addition to the aforementioned facts, the evidence discloses that shortly after the operation the plaintiff became concerned over the length of time it was taking that area to heal and that he asked the defendant about it, the latter replying, ". . . he had a hard job getting it out, and the bone might be chipped, or something, there." As heretofore stated, the plaintiff did not again return to the defendant until the year 1938 or 1939, at which time he informed the doctor of his troubles, particularly as to the periodic swelling of his gums. The defendant then x-rayed all of his teeth and jaw and told him that there was nothing there that would give him any trouble. Plaintiff further testified that until he went to Dr. Knower in December 1941 or January 1942, he had completely relied on the representations made to him by the defendant that there was nothing about his jaw that should cause him trouble. The defendant knew, or was chargeable with knowledge, of the breaking of his instruments and the great probability of the parts lying within the jaw and gums of the plaintiff. In the circumstances any conduct other than immediate action by the dentist either to remove the broken parts of his instruments or to alleviate the condition, so as to prevent any harmful consequences, or full and frank disclosure to the patient of the true facts, so as to enable the latter to take steps to correct the condition, was fraudulent concealment amounting to legal or constructive fraud. Constructive fraud, said the court, arises out of a fiduciary or confidential relationship. Such nonaction and nondisclosure as was present here was a clear breach of the close confidential relationship which of necessity exists between dentist and patient.

The legal or constructive fraud which was present in this case continued in effect during the time subsequent to the operation on the plaintiff to and until the time the plaintiff became apprised of the true condition existing within his mouth, or by the exercise of reasonable diligence should have learned the cause of his illness. Until the plaintiff's visit to Dr. Knower in 1941 he was unaware of the presence of the metal in his jaw. He had endeavored to ascertain the cause of his illness on many occasions, and he had consulted several medical doctors without success. Plaintiff's reliance on the statements made to him by the defendant in 1935 and 1938 or 1939 in regard to the condition of his jaw constituted sufficient reason for not consulting another dentist in regard to any swelling which had been periodically recurring. As this action was instituted by the plaintiff within six months after his discovery of the true facts which constituted his cause of action, the case falls within the rule set out in the former decision handed down in this case and is not barred by the statute of limitations. ". . . we hold, therefore, that fraudulent concealment by one occupying a position of trust tolls the running of the statute of limitations until the other party discovers or is put on reasonable notice of the breach of trust regardless of the form of the action. We think this rule is both reasonable and just. . . ." Accordingly the judgment in favor of the plaintiff was affirmed.—*Morrison v. Acton, 198 P. (2d) 590 (Ariz., 1948).*

# Current Medical Literature

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Id.: III. Epidemiological Pattern and Effect of Ultraviolet Irradiation During Winter of 1946-1947. A. D. Langmuir, E. T. Jarrett and A. Hollaender.—p. 240.

**Protective Antibodies in Syphilitic Patients.**—Turner and his associates state that one of them had previously reported experiments which showed that serum from syphilitic rabbits when combined with virulent Treponema pallidum, incubated in vitro and injected intradermally in normal rabbits, exerted a protective action against the development of a local syphilitic lesion. This suppressive action appeared to be due to an antibody of the nature of protective or neutralizing antibodies which develop in the serum of animals and man during many bacterial and virus infections. The authors report results of so-called protection tests performed in a similar manner with serum from human beings. Serum specimens were obtained from patients with primary syphilis, secondary syphilis, previously untreated latent syphilis, treated latent syphilis and tertiary syphilis and from a group of persons without syphilis. Specimens from a group of healthy persons served as additional controls. Serums from patients with secondary, latent or tertiary syphilis exerted definite inhibitory effect on the development of syphilitic lesions as compared with serums from nonsyphilitic patients or from the normal pool. This effect was manifested by complete suppression of lesions at the site of inoculation of serum-spirochete mixtures, or by prolongation of the incubation period and by smaller average size of lesions. Serums from patients with primary syphilis held a somewhat intermediate position, but in general behaved more like serum from nonsyphilitic persons. It is concluded that persons with secondary, latent and tertiary syphilis possess humoral antibodies which kill, or at least inhibit, the multiplication of, T. pallidum and that these protective antibodies probably play a significant role in acquired immunity to the disease.

**Ultraviolet Radiation of Sleeping Quarters.**—DuBuy and his co-workers evaluated the effectiveness of ultraviolet radiation for the control of the common cold and similar infectious diseases of the upper respiratory tract, considered to be air borne, among the occupants of the National Training School for Boys. The study extended over six years. The amount of radiation during the last two years was about five times that recommended commercially. The general bacterial population in the radiated dormitories was sometimes higher, sometimes lower, than that of the control dormitories. The data imply that the air layers are not efficiently mixed. More efficient mixing might have been obtained at the expense of a materially increased chance of raising dust and lint. The disease incidence among the inhabitants of the radiated dormitories was sometimes higher, sometimes lower, than that of the control dormitories, with no evidence that ultraviolet radiation consistently effected a reduction in disease incidence. Since no significant effect of ultraviolet irradiation in controlling incidence of disease could be detected among about 400 inmates during six years, the beneficial effect of ultraviolet installations for general population use is questioned.

**Pregnancy and Subacute Bacterial Endocarditis.**—Mendelson states that 10 cases of subacute bacterial endocarditis complicating pregnancy were recorded among 50,000 patients at the New York Lying-In Hospital from 1932 through 1947. The incidence of this complication is 0.02 per cent. Three cases with positive blood cultures occurred before the use of penicillin, and the 3 patients all died during pregnancy or the puerperium. Seven patients, treated with penicillin, survived pregnancy and delivered normal living children. Two of the penicillin-treated patients had clinically authentic subacute bacterial endocarditis during pregnancy, unconfirmed by positive blood cultures. In 5 of the penicillin-treated patients presence of the disease was proved by positive blood cultures: Three had recently recovered from the disease prior to pregnancy, and in 2 the disease developed during pregnancy. These 5 cases suggest that the past history of subacute bacterial endocarditis is not necessarily a contraindication to a subsequent pregnancy. Pregnancy should be deferred until the valvular disease has resolved. The advisability of childbearing should then be determined by the cardiac status, and accepted concepts of the management of the underlying rheumatic or congenital heart disease followed during pregnancy, delivery and the puerperium. The type of delivery should be determined primarily on obstetric indications. There is insufficient evidence to suggest that the development of subacute bacterial endocarditis during pregnancy significantly alters this same management. Anticipation of delayed valvular damage may justify interruption of early pregnancy despite current adequate cardiac reserve. Pregnancy does not alter the treatment of subacute bacterial endocarditis. The antepartum use of anticoagulants may endanger the fetus. Normal blood coagulation values should not be disturbed at the time of delivery or in the early puerperium. The prophylactic use of antibiotics during labor and the early puerperium may prevent the development or recurrence of subacute bacterial endocarditis in patients with rheumatic or congenital heart disease.

**Chronic Ulcerative Colitis and Pregnancy.**—Felsen and Wolarsky report on 34 women who had fifty pregnancies while they had chronic ulcerative colitis. These 34 women were part of a group of 783 patients who were under the care of the authors for chronic ulcerative colitis. Seven pregnancies in 5 patients did not proceed to term, three because of operative intervention. All occurred before they were seen by the authors. Pregnancy was not adversely affected in the remaining 43 instances, but was full term and resulted in live births. In nearly three fifths of the pregnancies the ulcerative colitis was definitely improved. It appears that termination of pregnancy is not indicated in the presence of chronic ulcerative colitis.

**Recent Developments in Water Balance.**—Robinson feels that administration of parenteral fluids is often carried out haphazardly, based on erroneous principles long discarded. In a canvass of fifty small community hospitals several abuses in the parenteral administration of fluids were rather generally encountered. The author points out the elementary considerations which must be kept in mind when administering fluids parenterally and discusses the various types of water imbalance. He gives a few specific examples of the proper choice of repair solutions. The first example is that of a patient in the first twenty-four hours following hysterectomy, who is not debilitated or dehydrated prior to the time of operation; the patient is not nauseated and is able to start taking fluids by mouth within a few hours after the operation. Parenterally she should not have more than 1 liter of dextrose solution to supply her water needs for the day. This may be given during the operation. The average normal patient needs parenterally only a sufficient amount of water to cover the insensible loss during the first twenty-four hours after the operation. The second example represents a similar postoperative patient, who is nauseated and vomiting after return from the operating room. A measurement of this patient's loss by vomiting should be made and replacement should be carried out, a dextrose solution in 0.6 per cent sodium chloride being used in amounts equivalent to the amount lost in vomiting. The third example concerns a patient who had undergone subtotal gastric resection. The patient should receive an amount of hypotonic (0.6 per cent) sodium chloride solution equivalent to that lost by the suction drainage. The remainder needed to cover the insensible loss plus the urinary output of the day before should be in the form of 5 or 10 per cent dextrose in water. If the patient has received blood in the operating room in the excess of that lost during the operation the need of saline solution will be proportionately reduced. The last example is that of a patient with a newly working ileostomy. This patient should receive as nearly as possible an amount of Hartmann's or isonate* (0.644 Gm. sodium chloride, 0.252 Gm. sodium bicarbonate and 0.018 Gm. potassium chloride per hundred cubic centimeters) solution equivalent to the amount of drainage from the ileostomy.

**Splenectomy in Splenic Neutropenia with Arthritis.**—After a brief review of the literature on Felty's syndrome since 1924, when Felty first described the syndrome of chronic rheumatoid arthritis associated with splenomegaly and leukopenia, Smith and McCabe cite 2 patients, a man of 52 and a woman aged 59, with primary splenic neutropenia and arthritis, who showed clinical improvement following splenectomy with a return to normal of the leukocyte count. The authors are not concerned whether they should label them as instances of Felty's syndrome or, by considering the arthritis as a coincidence, to classify them as primary splenic neutropenia described by Doan and Wiseman. In regard to the mechanism of production of the leukopenia of pancytopenia these 2 cases appear to lend no support to the theory of Doan and Wiseman that the blood cells undergo "sequestration" and phagocytosis by the hyperactive and enlarged spleen. The first patient differs somewhat from those described by Doan in that the bone marrow was hypoplastic rather than hyperplastic. This absence of hyperplasia gave the authors much concern regarding the advisability of splenectomy, since they feared that the removal of the spleen would be of no avail in the face of what appeared to be a poorly functioning bone marrow. The authors now feel that the cases which show a decrease in the cellularity of the bone marrow probably represent the same clinical entity in a different stage of the disease. It is possible that the marrow may previously have been hyperplastic, but owing to the prolonged duration of the disease the bone marrow became exhausted (hypoplastic). Splenectomy is of value even in the presence of a hypoplastic bone marrow.

**Löffler's Syndrome.**—Ham and Zimdahl present 3 cases of pulmonary infiltration with eosinophilia. The first case had a long, stormy course which did not resemble the typical Löffler syndrome. The second case had a less severe but rather protracted course with onset suggesting angina pectoris. The third had a prolonged course with two episodes, and of the 3 cases it was the only one with a definite background of hypersensitivity. Since Löffler's original report on the syndrome of pulmonary infiltration with peripheral eosinophilia, a great many conditions with superficial resemblance to the syndrome have come to be described under that name. This seems rather unfortunate in that it tends to imply that it is a disease with varied clinical manifestations and definite causation, rather than a restricted symptom complex of unknown and possibly varied etiology. No etiologic agent was found in these cases. There may be a specific allergen to which the patient is sensitive or there may be a parasitic infestation which will respond to specific therapy. In case of an allergic background or a stormy course, it must be borne in mind that epinephrine or aminophylline may alleviate the course. The authors make a plea for a more useful and standard nomenclature.

**Hand-Schüller-Christian Disease.**—Schuknecht and Perlman point out that in destructive lesions of the skull the xanthomatous diseases must be considered. They report 7 cases. Three of the patients had initial destructive lesions of the temporal bone. Their condition was classified as Hand-Schüller-Christian disease. The remaining 4 patients had solitary granulomas elsewhere in the skull. The temporal bone may be the site of early lesions in Hand-Schüller-Christian disease. When small, these lesions are silent. As the lesion grows in size, it may manifest itself in several ways: by perforation of the external auditory canal wall; erosion through the cortex of the mastoid, zygomatic and squamosal portions of the temporal bone; invasion of the labyrinthine capsule; involvement of the facial nerve; encroachment on structure in the jugular foramen, or secondary infection. When exuberant xanthomatous granulations invade the external auditory canal, they do so by passing through the canal wall and not through a defect in the tympanic membrane. When granulations appear in the external auditory canal, the diagnosis can usually be made by microscopic examination of this tissue. Uncomplicated lesions of Hand-Schüller-Christian disease or eosinophilic granuloma of the temporal bone are almost always painless, but secondary infection frequently occurs in such a diseased temporal bone. This may occur via the eustachian tube after an infection of the upper respiratory tract or through a fistulous tract in the external auditory canal wall. When this happens, the primary disease process is often overlooked. An important clue is the roentgenographic evidence of bone destruction out of all proportion to that which one would expect from the duration and degree of infection. When the nature of the lesion is suspected, it is important to seek roentgenographic evidence of other skeletal or visceral lesions. Positive biopsy diagnosis of eosinophilic granuloma or Hand-Schüller-Christian disease must be made before irradiation is given. Eosinophilic granuloma is a milder form of the basic disorder underlying Hand-Schüller-Christian disease. It usually manifests itself by a single bone lesion. Either surgical removal or irradiation of eosinophilic granuloma results in a cure of that lesion. Because it is necessary to establish the diagnosis by biopsy, it is common procedure to remove the entire lesion at the time of surgical treatment. When other lesions exist or subsequent lesions occur, they can be treated by irradiation.

**Pulmonary Aspects of Fibrocystic Disease of Pancreas.**—According to Atkins fibrocystic disease of the pancreas is characterized by an absence or diminution of pancreatic enzymes, poor utilization of protein, starch, fat and fat-soluble vitamins and the passage of large, foul, fatty stools. It develops in early childhood. Respiratory symptoms sometimes dominate the clinical picture and resemble chronic respiratory infection due to other causes. The author presents the histories of 3 children. The roentgen examination of the chest of these children frequently fails to demonstrate changes commensurate with the degree of functional disturbance. Increased hilar density with exaggeration of hilar markings is seen. Mottling of the lung fields, localized infiltrations, widening of the mediastinal shadow or emphysema may be associated with these. Bronchoscopic examination of the children presents fairly characteristic findings. A few may present the picture of tracheobronchitis with the usual moderately thin mucopurulent secretion. The common picture is that of a hyperemic sometimes granular mucosa with thickening of the bronchial spurs. On introduction of the bronchoscope the lumen is obscured by the presence of extremely viscid, purulent or, occasionally, blood-stained mucus. When this is aspirated the hyperemic bronchus shows expiratory intrusion of the posterior bronchial wall into the lumen. Bronchoscopic aspiration gives symptomatic relief and may aid in prolonging life.

**Exophthalmos and Its Surgical Treatment.**—Naffziger demonstrated that ocular protrusion is due to great enlargement of ocular muscles. A decompression of the bony orbit prevents further progression. The pathologic changes responsible have been confirmed by many, and the treatment has been widely followed in many clinics. Orbital decompression, although carrying little risk, is a procedure of such magnitude that it is reserved for cases of considerable gravity. Thirty-nine patients have come to the operation of orbital decompression, many after long observation and efforts at medical treatment. In these the indications for operation have been threatened loss of vision from danger to the cornea, choked disks or unchecked progression of proptosis which had reached the danger point. The surgical treatment consists of enlarging the orbital space to accommodate an increased mass of tissue. The use of thyroid substance or thyroid and iodine in the treatment of progressive disease seems to be of some help in controlling the progression and in promoting water excretion and lessening its storage, though the results are not striking. Efforts at reducing pituitary function by the use of high voltage roentgen therapy have given varying results. Spinal puncture and diuretics have accomplished little in the presence of orbital edema. Locally, sponge rubber compression pads may be worn at night to lessen the congestion and additional swelling noted after a night's sleep. Limitation of fluids has been of help.

*Chondromyxoid Fibroma of Bone: Distinctive Benign Tumor Likely *to be Mistaken Especially for Chondrosarcoma.* H. L. Jaffe and L. Lichtenstein.—p. 541.

**Extra-Abdominal Desmoid Tumors.**—Musgrove and McDonald point out that the term desmoid tumor is applied to a hard, fibrous tumor occurring in the abdominal parietes. The term has also been employed to indicate similar tumors occurring elsewhere. The present study is based on a clinicopathologic examination of 34 extra-abdominal tumors which were removed surgically at the Mayo Clinic. In addition, an equal number of tumors diagnosed as low grade fibrosarcoma were taken at random from the files and studied microscopically, in a similar manner, in an attempt to draw up differential histologic and cytologic criteria between the desmoid tumor and fibrosarcoma. The extra-abdominal desmoid tumor is the same pathologic entity as the desmoid tumor occurring in the musculoaponeurotic structures of the abdominal wall. It is a benign fibrous neoplasm, which has the peculiar characteristic of locally invading and destroying the adjacent striated muscle. It does not metastasize, and there is no evidence that it undergoes sarcomatous change. Two theories of origin have been presented, namely, that of a relationship to trauma and that of an endocrinologic basis. Fourteen of the 34 patients definitely linked the onset of the tumor with some previous trauma. However, only 3 of the 34 tumors showed a trace of hemosiderin. Thus, the histories tend to corroborate the traumatic etiologic basis, while the microscopic observations tend to disprove it. There is strong evidence that the endocrine glands may play a part in the origin and "physiology" of these tumors. Desmoid tumors occur more frequently in women than in men, the ratio in this series being 2.4 to 1. The authors mention microscopic criteria that are important in the differentiation of the desmoid tumor and low grade fibrosarcoma. Desmoid tumors should be treated by radical excision. It is doubtful whether roentgen rays and radium are of value. The rate of recurrence in the 34 cases of extra-abdominal desmoid tumor was high, calling for a reassessment of the surgical and radiation forms of therapy and for more research in, and clinical trial of, endocrine therapy. Endocrine therapy holds out hope in the inoperable cases, but there is much to be learned about this form of therapy.

**Chondromyxoid Fibroma of Bone.**—Jaffe and Lichtenstein encountered a rather distinctive benign tumor of bone the anatomic peculiarities of which seem best expressed by "chondromyxoid fibroma." The lesion first impressed itself on the authors when they were reviewing their material on chondrosarcoma. To date they have observed 8 cases of chondromyxoid fibroma. The tumor apparently has not been generally recognized in the past as a distinctive neoplasm, although it appears likely that in single instances it has been reported as enchondroma and myxoma, or their cancerous counterparts. The authors interpret the lesion as a peculiarily differentiated connective tissue tumor, exhibiting certain chondroid and also myxoid traits. It is composed of cells lying loosely in a myxoid intercellular matrix which, as the tumor matures, may undergo collagenization. The tissue may also come to simulate cartilage tumor tissue in some or many fields, and in its gross appearance it likewise bears a certain resemblance to cartilage. The presence of cells exhibiting nuclear atypism may cause the lesion to appear more ominous than it is known to be, explaining why it may come to be diagnosed as a malignant tumor, particularly as chondrosarcoma. The lesion has been found so far only in the bones of the lower extremity. Most of the patients were adolescents or young adults. The lesion evolves slowly. The roentgenographic picture has a certain distinctiveness, at least when the lesion is in a long bone and has attained appreciable size, although there may be difficulty at times in differentiating it from bone cyst, enchondroma or a focus of fibrous dysplasia, without examination of tissue. The tumor is apparently entirely benign and does not tend to recur after curettage.

Evaluation of Colorectectomy and Immediate Anastomosis of Rectum. R. R. Best.—p. 681.

**Prolapse of Rectum.**—According to Hunt a rectal prolapse, or procidentia of the rectum, may be classified as mucosal or complete. The mucosal type is an evulsion of the mucous membrane and does not involve a descensus of the entire rectum. The mucosal form is common in old persons with relaxed sphincters and hemorrhoids. True prolapse or herniation of the rectum is a descensus of the entire rectum. This results when a pouch of peritoneum in the cul-de-sac or rectovesical space pushes its way through a weak area of the pelvic fascia. In a mucosal prolapse the protruding mucosa is smooth, while in true prolapse it is wrinkled. This condition can be approached from within the abdomen or externally. The procedures within the abdomen are directed toward obliteration of the cul-de-sac or rectovesical space by multiple purse string sutures of nonabsorbable material, together with a suspension or fixation of the uterus in women. This is the principle of the Moschowitz operation. The author also comments on Mayo's contribution, the Lockhart-Mummery, the DeLorme, the Graham and the Pemberton and Mixter procedures. The case of the man described in this paper did not lend itself to any of these procedures. The hernial defect was too large. The mass of prolapsed rectum was 8 inches (about 20 cm.) in length and 18½ inches (about 47 cm.) in circumference. The surface was in part covered by extensive leukoplakia, the true cell structure of which was questionable. A posterior rectal excision and a pull-down type of operation might have been successfully done, but the author preferred an abdominal to a perineal colostomy. An abdominoperineal resection has given good results and has permitted the patient to return to a gainful occupation. The posterior operative site is well healed, and there is no hernia. The colostomy functions well.

**Pigment Nephropathy in Battle Casualties.**—Progressive oliguria and anuria in battle casualties resuscitated from shock, and apparently on the road to recovery following extensive surgical procedures, caused the death of a significant number of severely wounded soldiers between the fourth and the eighth day after the wound was incurred. At necropsy the kidneys were somewhat enlarged, and pigment casts were seen in the distal convoluted and collecting tubules. Necrosis of the distal tubules was observed, with some inflammatory reaction in the adjacent stroma. Some cases showed slight swelling of the cells in Bowman's capsule. This lesion has been variously termed pigment nephropathy, hemoglobinuric nephrosis and lower nephron nephrosis. A study of the 99 cases in which pigment nephropathy was known to be present forms the basis of this report by Snyder and Culbertson. In all but 5 cases there was evidence that shock had existed. In 4 of the 5 nonshock cases there was evidence of poisoning due to sulfonamide drugs, crush injury or transfusion reaction. The authors discuss possible causative factors, and refer to recent experimental work. They conclude that pigment nephropathy occurs with a variety of conditions. In battle casualties, the renal damage is probably dependent on renal ischemia plus the excretion of pigment. The renal ischemia is vasoconstrictive in origin. The pigment may be myoglobin or hemoglobin. The hemoglobin may be from transfused blood or intravascular hemolysis. The role of infection should be investigated, and the influence of various anesthetic agents should be studied. Treatment should be prophylactic. Shock should be combated vigorously, with prompt restoration of the volume of blood. This should be accomplished with the proper medium, which for most battle casualties is whole blood. Treatment with oxygen is of value in combating anoxia. Injudicious use of sulfonamide drugs should be avoided, and discontinuance of their use in conditions predisposing to nephropathy should be considered. Dehydration should be avoided or corrected as promptly as possible. Thorough surgical removal of all devitalized tissue and foreign bodies and provision of adequate drainage to infected areas are important.

**Cause of Hemorrhagic Diathesis in Man.**—Conley and his co-workers report 3 male patients between the ages of 38 and 67 in whom a hemorrhagic diathesis with prolonged clotting time was associated with the presence of an anticoagulant in the blood. The anticoagulants appeared to be different in each of the 3 cases. There was no family history of hemorrhagic tendency and no previous history of abnormal bleeding in 2 of these patients, while the third patient was hemophiliac. In this patient precipitins against antihemophilic globulin could not be demonstrated, but a relationship between previous transfusions and the production of the anticoagulant seems not unlikely. One of the 2 patients whose anticoagulant resembled that of the hemophiliac in its mode of action had not received transfusion prior to his coagulation disorder. His anticoagulant must have been produced by some other mechanism. The clotting inhibitor of the second nonhemophiliac patient was different from the others in its mode of action. The anticoagulant in each patient was relatively heat stable, nondialyzable and probably protein in nature. The anticoagulants of the hemophiliac and of the patient whose anticoagulant resembled that of the hemophiliac did not appear to be antithrombic or antithromboplastic. Their action, therefore, must precede the liberation of active thromboplastin in the blood. It seems probable that they exert their effect by preventing the conversion of a thromboplastin precursor to its active state. The clotting inhibitor in the plasma of the second nonhemophiliac definitely delayed the conversion of prothrombin to thrombin even in the presence of an excess of active thromboplastin. The cases reported emphasize the importance of performing anticoagulant assays on the blood of patients with prolonged clotting times.

**Clinical Manifestations of Severe Diphtheria.**—Fisher and Cobb report clinical and laboratory features observed in 30 patients between the ages of 3 and 70 with the severe or the malignant type of diphtheria. Twenty-one of the patients died. There was clinical evidence of myocardial involvement in 27 patients; this was usually, but not always, verified in the cases in which necropsy was performed. Cervical adenitis was accompanied by a pronounced edema resulting in the so-called bullneck appearance in 18 patients. It has not been found to be due to bacterial invasion, and it would seem that this reaction is caused by local spread of the toxin. Laryngeal or tracheobronchial obstruction was encountered in 15 of the patients and was nearly always relieved by prompt tracheotomy and suction. Twelve of the 30 patients had a previous history of immunization against diphtheria. Similar experiences have been reported in other outbreaks. The inaccuracy of the virulence test as routinely employed is indicated by the fact that 6 of the 30 strains of diphtheria bacilli isolated were reported as avirulent. The average duration of the acute infection from its onset to the time antitoxin was given was 4.7 days. This delay in therapy was probably the most important cause of serious complications or death. Stress is laid on the urgent necessity of suspecting the possibility of diphtheria in all questionable cases, so that the diagnosis may be made early and specific treatment administered promptly.

Surgical Treatment of Cancer of Cervix Uteri (Radical Operation for Cancer of Cervix). A. Brunschwig.—p. 672.

**Venous Thrombosis and Pulmonary Embolism.**—Allen and Donaldson report on 2,667 patients who received some form of specific measures at the Massachusetts General Hospital for the prevention or the treatment of the thromboembolic syndrome. In this group of cases there were 12 deaths related to the process toward which the treatment was directed. General prophylactic measures only were used in most patients under the age of 30. Specific treatment was indicated in a few of these because of the previous history of phlebitis or the type of lesions present. Therapeutic specific measures were carried out when indications of thrombosis or infarct occurred. Four hundred and ninety-six patients between the ages of 40 and 65 were treated prophylactically with small doses of dicumarol® postoperatively. None of these died of pulmonary embolism. Bleeding from suture lines and a tendency of large dead spaces to fill with blood after the use of dicumarol® were noted. The authors believe that anticoagulants cannot be safely used empirically and that careful laboratory and clinical control is necessary. Prophylactic bilateral superficial femoral vein interruption, as close to the profunda femoris vein as is technically possible, was done on 871 patients whose age of 65 or over, debility or disease indicated that in a high percentage of them thrombosis of the veins of the legs would be likely to develop. Of these patients 4 died subsequently of pulmonary embolism. This was a highly vulnerable group of patients and, on the basis of comparable experience, 37 deaths from embolism might have been expected. Of 1,260 patients treated by phlebotomy, thrombectomy and femoral vein interruptions after signs or symptoms indicated that thrombosis had occurred 6 died of further emboli. It is estimated that 60 of these might have succumbed if specific therapy had been withheld. In a small percentage of these patients anticoagulants and lumbar sympathetic procaine blocks were also used. Deaths from sudden pulmonary embolism still occur in untreated patients in the Massachusetts General Hospital in spite of alertness to the possibilities. As a result of the diminished mortality from shock, infection and pneumonia in recent years thrombosis and embolism have become a more prominent cause of death than formerly noted.

**Postoperative Venous Thrombosis.**—Mahoney and Sandrock determined the prothrombin activity of plasma, using Quick's one stage method in 68 postoperative patients. In 10 of these patients thrombosis developed, while the remaining 58 had no complications. Most of the patients selected were over 50 years of age and were undergoing major abdominal or chest operations, or had a history of previous thrombophlebitis. After operation the prothrombin activity decreased (prothrombin time increased) during the first three days; the lowest level usually occurred on the third day. After the third day the level increased, and returned to normal about the sixth day. In young persons there was a more rapid return to the preoperative level and the curves were more variable. There is less variation in the results obtained with whole plasma than with dilute plasma. The prothrombin activity of the 10 patients in whom thrombosis developed varied much more than the normal values on the first and second days and was in general above normal. It was above 100 per cent on the second and third days. The increase in prothrombin activity was usually abrupt; it was significantly higher in every instance than the values obtained in normal patients. In this group of 10 patients, only 5 were treated with anticoagulants. In some untreated patients the prothrombin values remained high after the third day, but in many the values returned to normal even though thrombosis was present. The hyperprothrobinemia which has appeared rather uniformly on the third postoperative day in patients who subsequently showed clinical evidence of thrombosis suggests that at this time the thrombotic process is just beginning in small veins. The increased prothrombin activity appears to be a transitory phenomenon and is a warning that changes are occurring in the blood which result in thrombosis. Increased prothrombin activity is suggested as an aid to the early diagnosis of postoperative thrombosis and as a basis for selecting patients who should receive prophylactic anticoagulant therapy.

**BAL in Treatment of Mapharsen Overdosage.**—Armstrong and his co-workers treated 2 men aged 30 and 31, respectively, who had syphilis and to each of whom were administered inadvertently the contents of a ten dose oxophenarsine hydrochloride vial (600 mg. of oxophenarsine hydrochloride or 174 mg. of arsenic) with BAL (2,3 dimercaptopropanol). An intramuscular injection of 3 mg. of BAL per kilogram of body weight was given as the initial dose within thirty minutes after the injection of oxophenarsine. This dose was repeated every four hours for the first two days, every six hours for the third day, twice daily for eight days thereafter and once on the twelfth and last day of treatment. At the end of the fifth day of the treatment the total amounts of arsenic excreted in the urine were 46.9 mg. and 51.9 mg. respectively. Neither patient showed striking signs of BAL toxicity or the visceral toxic effects usually attributed to arsenic poisoning. After completion of the treatment both patients remained entirely asymptomatic except for a slight scaly exfoliation of the skin of the hands and feet in one of them. BAL therapy completely counteracted the effects of the 600 mg. dose of oxophenarsine hydrochloride.

**Treatment of Duodenal Ulcer.**—Stevens presents a preliminary report on the combined procedure of conservative gastric resection and partial vagotomy in a series of patients with duodenal ulcer. The purpose of the combined treatment is to attack both the hormonal and the nervous phase of the secretion of gastric acid without removal of the duodenal ulcer itself. Vagus fibers on the lesser curvature of the stomach were included in a mass ligation and division of the coronary artery high up on the lesser curvature. According to Dragstedt this should include at least 75 per cent of the fibers of both vagus nerves. This procedure is simple and brief. Approximately one half of the stomach, including the pyloric portion, was removed rather than the conventional three fifths. The postoperative reduction of gastric acid was more consistent than that following complete double vagotomy alone. In 10 patients of this series the free hydrochloric acid was reduced from an average of 43.8 per cent preoperatively to an average of 2.6 per cent, as compared with a reduction of free hydrochloric acid from an average of 44 per cent preoperatively to an average of 9.7 per cent postoperatively in 10 patients with complete vagotomy. The data on the 10 cases are typical of the series as a whole. Insulin tests showed a reduction of free hydrochloric acid from an average of 69 per cent preoperatively to an average of 17 per cent postoperatively. This suggests that partial vagotomy as executed in this series is effective. The stomach was divided at or just below the gastroduodenal junction. Rather than dissect the posterior wall of the duodenum, which heals poorly, from the head of the pancreas, the capsule of the pancreas, which heals rapidly, was used as a reinforcing layer in the closure of the duodenal stump. There has not been any leakage of the duodenal stump.

**Cutaneous and Epidemic Diphtheria.**—Stern reports an epidemic of 133 pharyngeal, cutaneous and combined cases of diphtheria in the Pacific in 1944. Thirty-three patients had shown negative reactions to the Schick test within two months previous to the onset of the disease. Indolent ulcers which give few symptoms may well act as a quiet source of virulent pharyngeal diphtheria. The typical ulcers observed by the author were generally round or oval, varied from a few millimeters to 4 cm. in diameter and had a sharply demarcated "punched out" appearance. The base was flat and usually fairly clean but at times covered with a thin, grayish fibropurulent layer or a thin dry crust. The lesions were painless except when situated in areas involved in motion. They were usually on the extremities at the site of previous trauma such as abrasions, insect bites or scratches. Often, when initial cultures from the lesions were negative for the diphtheria bacillus, positive cultures were obtained after sterile wet saline compresses had been applied from eight to twenty-four hours. These ulcers when healed presented another characteristic observation in that the scars were usually hypesthetic or anesthetic to pin prick. Penicillin is of no proved use in diphtheria except in clearing of the pharyngeal carrier state and hastening the healing of cutaneous ulcers. Penicillin solution of 500 units per cubic centimeter on moist compresses was of definite value in shortening healing time of the cutaneous lesions.

**Liver Biopsy and Liver Function Study.**—Mateer and his associates compared in 132 patients operated on for cholelithiasis, and in 31 patients operated on for peptic ulcer, the results of biopsy of the liver at the time of laparotomy with the results of preoperative functional tests of the liver. This is a study of very early hepatic disease. The majority of the 163 livers appeared normal at biopsy, and 121 of the patients failed to present clinical evidence of hepatic disease before operation. All biopsy tissue was obtained either from an area in the right lobe of the liver far distant from the attachment of the gallbladder or from the left lobe. The interior of deep "wedge" biopsy specimens from the edge of the liver seemed to provide slightly more representative microscopic information than needle biopsies. Wedge biopsies were obtained in all 163 cases and needle biopsies in 55 cases. Only 6 per cent of the patients with gallstones and only 7 per cent of the patients with peptic ulcer revealed normal livers on histologic study. Microscopic periportal cirrhosis and acute infiltrative hepatitis were the two most interesting conditions encountered in the histologic studies. The periportal cirrhosis which is characterized by an abnormal increase in the fibrous stroma and by a mononuclear infiltration of the stroma occurred in 33 per cent of the gallstone cases and 29 per cent of the peptic ulcer group. Acute infiltrative hepatitis characterized by a polymorphonuclear infiltration of the hepatic parenchyma was seen in 15 per cent of patients with gallstones and in 10 per cent of the patients with peptic ulcer. The degree of positiveness of the reactions to the six hepatic function tests was greater in the patients with cholelithiasis than in those with peptic ulcer. In most of the tests there was a greater percentage of positive reactions associated with the presence of parenchymal cell abnormalities than with their absence. In the individual case, however, no deduction regarding the parenchyma can be drawn from a positive reaction, since an appreciable number of positive reactions are associated with normal parenchymal cells. Information regarding function and biopsy evidence regarding morphology must be considered as separate items of diagnostic information, both of which should enter into the appraisal.

**Gastric Mucosa After Vagotomy.**—To evaluate the effect of vagotomy Asher made gastroscopic studies on 20 patients. Eight of the patients had transthoracic vagotomy only, and 12 had vagotomy with either pyloroplasty or gastroenterostomy. In the series there were 11 patients who had one or more preoperative gastroscopic examinations. Postoperative examinations were made at intervals of three to twelve months. In several cases, the postoperative examinations were repeated. Vagotomy produced definite changes in the gastric mucosa in three fourths of the patients. Hypertrophic gastritis often associated with superficial erosions was the change seen most frequently. It is felt that the changes which occur as a result of vagotomy influence the development of gastritis. These changes consist of: (a) altered circulation, (b) altered secretion of mucin together with dissociation of acid and mucin secretion and (c) altered motility. These changes perhaps reduce the resistance of the gastric mucosa to physical trauma. Thus it appears that the operation which primarily separates the gastric mucosa from psychic trauma makes it more susceptible to physical trauma.

**Electron Microscope Studies on Varicella and Herpes Zoster.**—Rake and his co-workers studied elementary bodies of varicella and herpes zoster viruses with the electron microscope In the vesicle fluid of the lesions of various clinical types of herpes zoster they found elementary bodies that resemble closely those found in varicella. These elementary bodies have been scanty in fluids withdrawn from twenty-four hours to six days after the first appearance of the rash. In 1 case in which fluid was obtained twelve hours after the appearance of the vesicles the elementary bodies were numerous. Fluid from this same crop of vesicles, withdrawn forty-eight hours later, showed few elementary bodies. In 1 instance vesicle fluid was examined from a case of herpes zoster that apparently initiated an outbreak of varicella. Fluid was also examined from 3 cases of varicella. Scanty but characteristic brick-shaped bodies were found in the fluid in all 4 cases.

**Hypertensin in Systemic Blood of Animals.**—Gollan and his co-workers eliminated the hypertensinase activity immediately after the withdrawal of the systemic blood of dogs by cooling the blood to 0 C. (32 F.). This was followed by immediate separation and precipitation of the plasma. By this procedure it becomes possible to detect any hypertensin present in the circulating blood at the time the specimen of blood is withdrawn. After the intravenous injection of 1 unit of renin into normal dogs, as much as 1 unit of a pressor substance was detected by this method in the plasma from 200 cc. of systemic blood. Large amounts of systemic blood pooled from several normal dogs did not contain detectable amounts of pressor substance. In experimental renal hypertension due to unilateral or bilateral constriction of the main renal arteries in dogs, a pressor substance was demonstrated in large amounts of systemic blood, corresponding to from one fifth to one third of the total blood volume. This was accomplished without the addition of hypertensinogen to enhance the action of the renin in the blood. In an animal weighing about 15 Kg. (33 pounds) with benign hypertension up to three months' duration, 3 to 5 units of this pressor substance are probably constantly circulating in the entire systemic blood. The pressor substance was also detected in a relatively small amount of renal vein blood from an ischemic kidney. In dogs weighing about 15 Kg. with experimental renal hypertension of the malignant type, from 15 to 25 units, or more, of the pressor substance are present in the entire circulating blood. The pressor substance which appears in the systemic blood of dogs with experimental renal hypertension, and of normal dogs after intravenous injection of renin, is destroyed by hypertensinase. The pressor substance from the systemic blood of dogs with experimental renal hypertension proved to have the same physiologic and chemical properties as hypertensin produced in vitro. It is therefore suggested that the name hypertensin be adopted for the pressor substance which causes experimental renal hypertension.

**Retention of Aerosol Particles in Respiratory Tract.**—Wilson and LaMer studied the retention of aerosol particles in the human respiratory tract as a function of particle radius and breathing rate, using monodispersed aerosols (uniform particle size) of glycerol and water containing a trace of radioactive sodium. Seven subjects inhaled the aerosol. "Alveolar retention" (smaller bronchi, bronchioles and alveoli) has been distinguished from total retention by the use of radioactive tracer technics. The aerosol was produced by condensation of glycerol vapor on sodium chloride nuclei containing the tracer element. Particle size was measured by means of the higher order Tyndall spectrums calibrated in terms of sedimentation rate. Data are presented for breathing rates from 5½ to 20 cycles per minute. The retention decreases linearly with increasing breathing. Relative alveolar retentions, which were measured with a Geiger-Müller counter placed in the axillary region, showed dependence on particle size. The alveolar retention exhibits a maximum with two peaks in the range 0.3 micron to 1.0 micron in radius. Maximum alveolar retention appears to be of the order of 45 per cent of the inhaled aerosol. The selection of aerosols in this range of particle size is indicated for maximum "alveolar retention" of therapeutic aerosols.

**Environmental Studies in Plants Using Beryllium.**—Eisenbud and his co-workers say that cases of disturbances resulting from the industrial use of beryllium have been reported from plants processing the ore, from plants manufacturing fluorescent lamps, among employees using beryllium oxide for ceramics purposes and among another group working with pure beryllium metal in a machine shop. The investigations here reported were conducted in all three of the American plants producing beryllium compounds from the ore and in a number of laboratories and shops engaged in research in the ceramics and metallurgy of beryllium. Over 500 air samples have been collected on filter paper and analyzed spectrographically. The compounds studied were beryllium sulfate, oxide, fluoride, hydroxide, metallic dust and beryl. Those shown to cause acute pneumonitis are the sulfate, fluoride, oxide and metallic dust. The hydroxide is thought to be capable of producing the acute disease due to its similarity to the oxide; this was not demonstrated conclusively, because no workers were found who had been exposed exclusively to the hydroxide. Beryl was not found to cause acute toxicity. The toxicity of the oxide appears to vary depending on particle size, surface area and temperature of processing. Many cases of acute disease have resulted from a single excessive exposure. An exposure of twenty minutes to the fluoride is known to have produced three cases of acute pneumonitis.

**Protection Against Radiation Hazards.**—Morgan says that the men who were responsible for the planning of the Plutonium Projects were forced to face the unpleasant picture of the past history of man's carelessness with regard to exposure to radiation. They were resolved to do the job safely. A Health Physics Division was created which was composed of physicists, chemists and engineers who have made a study of radiation and have developed means of preventing radiation damage to persons engaged in atomic energy operations. It seems that the tolerance level of 0.1 r per day chosen five years ago for the Plutonium Projects is not as low as it should be. A recent analysis of some of the personnel radiation exposure records indicates that no employee is averaging more than 0.02 r per day. The projects have been concerned with exposures, not only to roentgen and gamma rays, but also to alpha, beta and neutron. Many precautions have been taken against excessive radiation exposure. Concrete walls, 6 feet (182.9 cm.) in thickness, are built around the pile to protect persons from intense neutron and gamma radiation. Radiating objects are withdrawn from the pile with long rods and the "hot" objects are pushed into lead coffins or dropped into a deep water canal. Chemical operations on radioactive materials are done behind shields. All the water and air discharged from the Plutonium Projects is checked constantly to make certain that the concentration of radioisotopes does not reach tolerance. The working areas are monitored constantly to see that the level of radiation is below tolerance. The best criterion of the success of this program is that to the present no one of the thousands of persons engaged on these Plutonium Projects and no one in the neighborhood of these projects has received any radiation damage.

**Hereditary Multiple Benign Cystic Epithelioma.**—According to Fliegelman and Kruse multiple benign cystic epithelioma is characterized by multiple, small, firm, often translucent, slightly coalescent tumors which show a decided predilection for the nasolabial folds, base of the nose, forehead, eyelids and about the ears; only occasionally are they found on the scalp, neck and upper part of the chest. The tumors are from a pinhead to a pea in size and usually are of normal skin color. They are often symmetrically distributed and show little or no tendency to ulcerate or to undergo malignant change. The lesions may remain stationary for a long time, then suddenly increase in both size and number. The disease is often hereditary. The authors present observations on a family group of which 22 members were examined and 8 were found to have multiple benign cystic epithelioma. Two more were reported to have the same disorder. The average age of onset in the 7 affected members of one sibship was found to be 11.5 years (9 to 17 years). There may be an association of café-au-lait-like spots with multiple benign cystic epithelioma. This study brought to light an Rh-negative mother who has had 11 Rh-positive children without a single instance of erythroblastosis.

**Effect of Mosquito Larvicide on Wild Life.**—Preliminary tests with DDT (dichlorodiphenyltrichloroethane) as a larvicide for the control of Anopheles quadrimaculatus mosquitoes demonstrated that this insecticide was toxic to fish and other forms of aquatic life. The U. S. Public Health Service, therefore, deemed it advisable to determine the over-all effects. Tarzwell describes the procedures employed and the results obtained. As a dust, routine applications of DDT caused little apparent damage to surface organisms. DDT dusts can be applied routinely at dosages of 0.1 pound (45.4 Gm.) per acre with little or no significant harm to wild life. Tight emulsions of DDT are more toxic to wild life than DDT fuel oil solutions. Routine treatments with fuel oil DDT solutions at dosages of 0.1 or 0.05 pound per acre generally kill large numbers of fish after the tenth treatment and with continued use greatly reduce the population of fish and fish food organisms. Routine treatments at discharge rates of 0.1 pound of DDT per acre had no significant effects on the reptile and amphibian populations. The natural driftage of DDT sprays and aerosols from water areas onto surrounding terrestrial areas had no harmful effects on bird and mammal populations during one season's treatments. No catastrophic or significant changes were produced in the terrestrial insect populations. Such treatments did not impair the strength of bee hives located on adjoining areas or decrease their production of honey. Routine treatments at discharge rates of 0.1 pound of DDT per acre as sprays or aerosols do not significantly change the populations of surface insects during one season's treatment. Although routine airplane treatments over a period of two years produced some fish kill, the total fish population was not changed and production in pounds per acre remained about constant. Routine airplane larvicide at discharge rates of 0.1 pound of DDT per acre is not significantly harmful to wild life at least during the first two years of treatment.

**Primary Pulmonary Cancer.**—Ochsner and his co-workers report 548 patients with primary pulmonary cancer who were admitted to hospital during the period of 1934 to 1948. One hundred and ninety-four (35.4 per cent) had inoperable lesions, 47 (8.5 per cent) refused operation and 307 (56.1 per cent) had exploration. The lesion was found to be resectable in 195 of the 307 patients (35.6 per cent). One hundred and sixty-three of these were male and 27 female. Positive results of bronchoscopic biopsy were obtained in only 74 (37.9 per cent) of the 195 patients with resection. This illustrates the diagnostic limitation of bronchoscopy and emphasizes the importance of exploration when all diagnostic methods yield only presumptive evidence of carcinoma. Forty-five of the 195 patients died at the hospital. Of the resections, 136 (70 per cent) were considered palliative rather than curative, since the lesions had extended beyond the confines of the lung. The gross survival rate after resection was 20 per cent at the end of three years, with little change up to five years thereafter. The survival rate in curative resections was considerably better than in the palliative group, but even in the latter a 10 per cent three year survival rate was observed. No patient survived three years among the cases in which resection was not performed. Lesions in the right lung had a higher fatality rate than in the left lung. Epidermoid and undifferentiated carcinomas occurred in a higher proportion in the older age groups than did adenocarcinomas. The distribution of histologic type was about equal among the younger age group. With increasing age at the time of operation there was a progressive increase in fatality, with a sharp increase in fatality in patients operated on after the age of 60. The most frequent type of tumor in men was epidermoid carcinoma, whereas in women it was adenocarcinoma. The survival rate over a five year period was consistently more favorable in women. The most favorable survival rate was found in patients with the epidermoid carcinoma and the poorest in those with undifferentiated carcinoma. Histologic grading of epidermoid and adenocarcinoma showed a good correlation with fatality. Among the undifferentiated carcinomas the small cell and oat cell tumors carried the lowest fatality and the large round-cell and clear-cell tumors the highest.

**Spontaneous Rupture of Esophagus.**—Kinsella and his co-workers report 5 cases of spontaneous rupture of the esophagus in 4 men between the ages of 67 and 74 and in an adolescent aged 16. All patients died. The correct diagnosis was made in 3 of the patients during life. One of the 3 was seen two weeks after the onset and in no condition for surgical intervention; in the second, surgical intervention was immediately considered but postponed because of the patient's grave condition in the fallacious hope that the condition might improve sufficiently to permit thoracotomy and repair. In the third patient open posterior thoracotomy was performed with the patient under intratracheal anesthesia with removal of food and stomach contents from the pleural cavity, a wide opening of the mediastinum and removal of food particles and fluid from it, followed by exposure of the ruptured area of the esophagus and closure of the perforation with nonabsorbable silk sutures. The patient survived nine days, but death resulted from pulmonary embolism. Spontaneous perforation of the lower part of the esophagus into the mediastinum or pleural cavity is always extremely grave. It would seem clinically that the early deaths must result from shock and tension pneumothorax; the later deaths apparently result from mediastinitis and pleural sepsis as well as from mechanical factors. Pain, collapse, vomiting, hydropneumothorax and emphysema should permit a diagnosis on historical and physical grounds alone in the majority of instances if the clinician is cognizant of the presence of such a condition. Early diagnosis, prompt surgical repair and proper postoperative treatment may be expected to save a considerable number of these patients from an otherwise certain fatal termination.

**Management of Injured Kidney.**—Lynch says that of 23 patients with renal injury admitted to the Charlotte Memorial Hospital, 13 had injuries classified as ruptures, 1 a stab wound and the remaining 9 contusions. Eleven of the 23 persons were injured in vehicular accidents, 7 in industrial accidents, 3 in athletics and 2 by weapons. All patients with acute ruptures of the kidney complained of severe pain and tenderness and rigidity of the flank, and about a third had a palpable mass. All of the 23 patients presented hematuria, 21 of them gross and 2 microscopic. In the 2 with microscopic hematuria the injury was classified as contusion, but mild or microscopic hematuria does not necessarily indicate a mild lesion, for a complete rupture of the vascular pedicle may result in no hematuria at all until the process of infarction begins. Seven of the 23 patients were operated on. Nephrectomy was performed in 4 cases, 2 injuries were evacuated of blood clots and drained, and in 1 case the rupture was repaired and drained. Six patients with rupture were not operated on; 1 of these expired of shock. Intravenous urography and retrograde pyelography are urged for complete and accurate evaluation of suspected renal injury. Exploration is advocated in all cases in which there is extravasation of intravenous or retrograde dye or obliteration of the renal and psoas shadows. The end of seventy-two hours is set as the ideal time to explore the kidney providing severe hemorrhage and shock do not require immediate operation. The ruptured kidney which is not explored, removed, repaired or drained is subject to a number of sequelae: secondary hemorrhage, extravasation of urine, infection, hydronephrosis, calculous formation and calcified cysts of the kidney. While the majority of injuries of the kidney heal spontaneously, the organ may later become functionless. The renal substance may heal but does so with the formation of a dense scar, so that a considerable portion of secretory tissue may be destroyed or a part of the kidney may suffer from insufficient blood supply. Cyst formation occurs in some, and some patients remain in poor health until a nephrectomy is done.

**Major Urologic Surgery on Patients in Respirators.**—Brady and Wilson believe that the 2 patients whose histories they present are the first to be taken directly from the "iron lung" to the operating room and to survive major urologic surgical treatment. A ureterotomy for calculi was performed on 1 of the patients; on the second, a ureterotomy for calculi and a nephrectomy. Both of these patients were anesthetized for fifty minutes. It would have been difficult to perform these operations if the patients had not been in an institution where there are respirators which can be taken directly to the operating room. The 2 patients were adult sisters in whom the bulbar-spinal type of anterior poliomyelitis developed within one week, and both were later operated on for stones in the urinary tract. Chemical analysis of the stones removed from 1 patient showed just a trace of calcium. In those from the second, not even a trace was present. This indicates that in these 2 women decalcification of the bones and excessive calcium intake played no part in the development of the calculi. The authors believe that the immobilization with defective drainage of some or all of the calices probably plays the most important role in the development of stones in recumbent patients. The 8 patients now in respirators at the authors' hospital have had negative roentgenograms with the exception of 1 girl, who has some gravel in one of the calices of the right kidney. Since she recently has been able to be out of the respirator for hours at a time, it is hoped that she will pass this, or attempts will be made to dissolve the calcareous material with solution G. Measures taken to reduce the likelihood of formation of calcareous material in those who have to be in respirators include a daily fluid intake of at least 3,000 cc.; only a glass of milk a day is permitted. Citrus fruits are given in only moderate amounts. Alkaline drugs such as sodium bicarbonate or alkaline saline cathartics are not used. The first morning specimen of urine is tested with nitrazine paper. If it is alkaline, ammonium chloride is prescribed for twenty-four to forty-eight hours. The reason for keeping the urine acid is that most of the stones in recumbent patients are made up of phosphates. Complaints of frequency of urination or dysuria are investigated promptly. When infection develops, sulfathiazole or sulfadiazine is prescribed, but never for more than one week at a time. When renal colic or pain in the flanks is complained of, roentgenograms are taken. Routine roentgenograms are taken at regular intervals. Frequent change in posture is of great importance in preventing formation of stones in recumbent patients.

**Rice Diet in Hypertension.**—Contratto and Rogers report a six month study of a group of nonhospitalized patients with hypertension who were treated with the rice diet. Of 55 patients, 34 cooperated and were considered satisfactory for evaluation. Each patient received a copy of the rice diet, as devised by Kempner, which contains in 2,000 calories not more than 5 Gm. of fat and about 20 Gm. of protein derived from rice and fruit and not more than 200 mg. of chloride and 150 mg. of sodium. A patient takes an average of 250 to 350 Gm. of rice (dry weight) daily. All fruit juices and fruits are allowed, with the exception of nuts, dates, avocados and any dried or canned fruit or fruit derivatives to which substances other than white sugar have been added. Usually no water is given and the fluid intake is limited to 700 to 1,000 cc. of fruit juice per day. Multiple vitamins were added. The diet was gradually modified for patients whose blood pressure readings dropped satisfactorily. The first modification was the addition of one egg once a week, half a cup of nonleguminous vegetables (carrots, broccoli, celery, cabbage, asparagus, beets, spinach and so forth), boiled without salt, once a day and, if desired, a cup of coffee or tea once a day, with sugar, but without milk or cream; no salt or fat was included in any of the modifications. The patient stayed on this regimen for two weeks to a month. If the blood pressure readings were satisfactory, 4 ounces of lean meat, fish, liver or chicken three times weekly was added to the diet, the egg being taken three times a week and the nonleguminous vegetable once a day. The meat or fish was boiled or broiled, without salt or salt-containing substances. The rice diet has been found to be a practical, inexpensive and simple method for reducing blood pressure.

**Lobectomy from Gunshot Wound.**—Holmes reports the case of a woman who had a pyramiding depression which terminated in a suicidal attempt, which she executed by holding a 12 gage shotgun under her chin and pulling the trigger. She was found in an unconscious state with a hole of entry in the midline of her chin about 1.5 cm. behind the symphysis. The hole carried up through the tongue, continued through the hard palate, the perpendicular plate of the ethmoid, both nasal bones, the frontal sinuses and part of the frontal bone as far as the hairline. After debridement and the use of penicillin, the patient gradually recovered. A psychiatrist believed that the patient was perfectly oriented, without a psychosis, and that she probably performed a partial anterior lobectomy, which had cured her pyramiding depression. Numerous corrective operations were carried out, of which the patient was most appreciative. She has resumed her place in her community. The author cites the famous crow bar-skull case, in which the head injury was similar to that in this woman. That patient, a miner, also recovered, and the chief residual lesion was a changed personality.

**Streptomycin in Dermatology.**—Combes and his associates cite reports and their own observations on the value of streptomycin in dermatologic conditions. Streptomycin is the antibiotic of choice in granuloma inguinale, tularemia and cutaneous infections due to Pseudomonas aeruginosa (B. pyocyaneus). It is of definite value in tuberculosis colliquativa, tuberculosis orificialis, chancroid, gonorrheal infections, infectious eczematoid dermatitis and cutaneous infections in which other antibiotics have failed or the patient presents an idiosyncrasy. It may benefit other forms of cutaneous tuberculosis, rhinoscleroma and leprosy. Systemic toxic reactions are not rare and may be serious but usually appear after weeks of therapy. Vertigo due to labyrinthine disturbances is not uncommon and may be annoying and permanent. Cutaneous reactions are of three types: (1) an early polymorphous biotropic type of exanthema appearing before the tenth day which responds to antihistaminics and does not require cessation of therapy; (2) an exfoliative dermatitis, appearing after many weeks of therapy and necessitating cessation of therapy, and (3) a troublesome contact dermatitis of high incidence, especially in nurses continually in contact with the drug over long periods, which necessitates the wearing of rubber gloves, frequent rotation of nurses or removal from further contact.

**Selective Placement of Industrial Workers.**—Sander asserts that now that the labor supply again is becoming more plentiful, a tendency to return to the prewar standards of overcareful selection of workers is beginning to appear. Experience in examining more than 50,000 workers in various industries has convinced him and his colleagues that outright rejection of more than 2 per cent of examinees is an unnecessary waste of man power. In one organization, which has plants in sixteen states, the rates of rejection varied from 0.5 to 20 per cent. Almost without exception, the high rates of rejection occurred in states in which compensation was being allowed for all varieties of alleged aggravation of preexisting disabilities and nondisabling defects. Another factor which tends to prevent the carrying out of true preplacement examinations is the rigid seniority rule of some labor unions. In one plant it was impossible to hire any one not able to do the heaviest kind of physical work, because everyone hired was required to start on such heavy laboring jobs. Another factor which has prevented the hiring of many workers with minor defects is the lack of funds for second injuries in most states. In such states, a man with only one good eye usually is rejected for most jobs, because, should he lose the good eye, the employer is liable for compensation for total blindness. Only three factors need consideration in the placement of a new worker at a job: (1) ability of the person to do the work, (2) safety of the job as related to the prospective employee's disability or handicap and (3) health of the prospective employee, for his own protection and that of the other employees.

**Implications of Health and Welfare Funds.**—Price believes that health and welfare funds may have a profound influence on the medicine of the future. Industry, labor, legislators and physicians have developed different plans to fit the need for health protection. The fact that each group concerned has a different approach indicates that the problem requires careful study. In the past, progress in providing some medical insurance and service has been achieved by many agencies. Enlisting subscribers for prepaid services has met resistance, but today there appears a highly organized clientele of millions of trade unionists, with huge cash reserves, ready and anxious to purchase health insurance and service. Are there enough physicians, properly oriented and trained, to serve this group? Industrial medicine has made strides in the departments of preventive medicine and public health. Industrial medical training is being developed more and more through undergraduate and postgraduate courses. Health and welfare programs will need the services of such physicians. Medical service will improve production as well as provide the workers with more health security.

Osteoporosis Associated with Pain. V. Laperrière.—p. 1210.

**Treatment of Bulbospinal Myasthenia.**—Thévenard and Léger treated 5 patients, 2 women aged 45 and 18, and 3 men aged 23, 46 and 55 respectively, with bulbospinal myasthenia gravis of two months' to eight years' duration, by denervation of the sinus caroticus. Surgical intervention was done with the patient under local anesthesia with procaine hydrochloride solution following basal anesthesia. The preoperative treatment consisted of ten days of rest in bed during which the optimum dose of neostigmine was determined. This dose and the rhythm of its fractional administration vary with every patient, and general posologic rules cannot be given. Subcutaneous administration of the drug seems to be preferable. The optimum dose of the drug should be increased on the day of the intervention and for the first forty-eight postoperative hours. The younger woman was the only one of the 5 patients to whom neostigmine was not given before the intervention, and she was also the only one in whom a grave respiratory disturbance occurred within eighteen hours after the intervention requiring administration of massive doses of neostigmine and sojourn in the iron lung for sixty-six hours. In 4 patients bilateral denervation of the sinus caroticus was performed at one month interval between the two interventions; unilateral intervention was performed in only 1 patient with a purely ophthalmoplegic syndrome, which is to be considered as a benign form or as a still favorable stage of the disease. The term "sthenic effect" has been coined to describe the favorable results of this surgical treatment on all the clinical manifestations of Erb-Goldflam's myasthenia. The localized muscular disturbances of paralytic appearance subsided completely or were improved considerably. There was much less tiring of the voluntary muscles, the nasal quality of the voice was corrected and the disturbances of deglutition and mastication subsided. Two patients could resume their physical activity, and the patient aged 23 was enabled to perform a march of 5 miles without fatigue. The severe preoperative respiratory disturbances in 2 patients did not recur for four years and sixteen months, respectively, after the intervention. The sthenic effect was manifested between the second and the thirtieth postoperative day, and it was progressive during the follow-up period of two months to four years; in only 1 patient was the manifestation of the sthenic effect delayed for three months after the second intervention. Early intervention and the patient's youth are two factors which favor a satisfactory postoperative prognosis. The concept that denervation of the sinus caroticus may produce hyperfunction of the adrenal cortex was not confirmed. That the doses of neostigmine required could be reduced considerably after the intervention suggests that the intervention is the active element in the combined treatment.

**BAL for Toxic Effects of Gold Therapy.**—Macleod reviews reports on BAL (2,3-dimercaptopropanol) with particular reference to its use in patients who had toxic reactions from gold therapy and reports 15 such cases. He gained the impression that BAL is of value in the treatment of these patients. In dermatitis the immediate improvement in the pruritus is a constant feature, and the course of the eruption is probably influenced in a favorable manner. BAL is also effective in the treatment of stomatitis and hepatitis due to gold. Toxic effects are minimal in doses up to 4 mg. per kilogram of body weight, except in cases of hepatitis, in which BAL must be given in smaller doses if severe reactions are to be avoided. The author investigated the possibility of an increase in the urinary excretion of gold coincident with the administration of BAL in 3 cases, but because the method used proved unsatisfactory it is not possible to furnish evidence as to whether the excretion of gold in the urine is or is not increased. Though relapse in the symptoms of rheumatoid arthritis following treatment with BAL has not been a feature of the present cases, it is probably undesirable to use BAL in quantities larger than necessary to control the toxic symptoms. It is suggested on the first sign of gold toxicity, other than hepatitis, and persisting in spite of stopping use of gold, that BAL may be given in a single intramuscular injection of up to 4 mg. per kilogram of body weight. The case can be reviewed from week to week or at shorter intervals, and further single injections of BAL may be given if necessary. BAL has been used in this way effectively in 4 cases in the present series. Where severe toxicity is present, such as exfoliative dermatitis, ulcerative stomatitis, and probably nephritis, agranulocytosis and thrombopenic purpura, more energetic treatment will be required. BAL could probably be administered with advantage in quantities up to 4 mg. per kilogram of body weight every four hours, omitting the night dose, for two or three days.

**Referred Pain.**—According to Sinclair and his co-workers none of the existing theories is capable of explaining all the observations which have been made on the subject of referred pain. From recent work on the anatomic mechanisms underlying various aspects of pain sensibility in the periphery, and on the mode of production of referred pain from the deep somatic tissues of the back, it is postulated that an essential factor in the production of referred pain is the existence of branching among the sensory pathways conveying the sensation of pain. This branching is of such a type that one limb of a branched axon passes to the site of origin of the disturbance, and others pass to the sites to which the pain is referred. This mechanism works in two ways: (1) by leading to a misinterpretation by the central nervous system of the true origin of the pain impulses and (2) by the liberation of metabolites at the terminals in the region where pain is experienced, thus giving rise to secondary pain impulses actually having origin at the periphery. In any given case, both mechanisms are concerned, the first being initially more important than the second, but the second increasing in importance with time and in the later stages preponderating. This theory rests on a basis of currently accepted anatomy and physiology, and is capable of explaining the numerous and sometimes divergent observations which have been made on the reference of pain from both somatic and visceral structures. It may require extension and amplification.

**Sjögren's Syndrome.**—According to Coverdale, Sjögren's syndrome indicates a general constitutional or systemic disturbance of unknown origin. Most cases appear in women at or after the menopause without any history of previous disturbance of the menstrual cycle. The extreme chronicity of the complaint suggests the possibility that the menopause is only an aggravating factor in a condition already established. The author describes cases with unusual constitutional factors. The first 2 cases presented are of a man and his daughter. The man, aged 68, had had a habit of sitting with his eyes closed when not at work. During this time he had also had a slight dryness of the mouth. He made no complaint of these disabilities until a few months ago when he had a cerebral hemorrhage with hemiplegia and his eyes became worse. He was found to have typical filamentary keratitis with Schirmer's test of 5 mm. in five minutes (control, 25 mm.). The filaments and much of the discomfort disappeared in a few weeks with no more than the application of petrolatum to the lid margins, though the deficient lacrimal secretion remained unchanged. A diagnosis of keratitis sicca may be preferred to that of Sjögren's syndrome. The daughter of this man had a lifelong history of dry eyes and showed signs of pituitary dysfunction. The third and fourth cases are of a woman and her daughter, the latter having pulmonary tuberculosis. The fifth case is of a young woman whose symptoms seemed to originate from a fracture of the base of the skull. Some of these cases illustrate a common and understandable vagueness about the time of onset. The progress is usually extremely slow and there is a considerable difference between the result of Shirmer's test in the normal subject and in the patient with signs and symptoms of keratoconjunctivitis sicca. A patient may show the syndrome in a fairly advanced state without being greatly inconvenienced and it is usually impossible even to infer when secretion began to fail. The author suggests that a congenital defect might be assumed which may be made manifest at any period of life by some aggravating circumstance. This suggestion is supported by Lisch's series in which 12 persons in three generations of one family showed some evidence of the syndrome.

**Tantalum in Traumatic Skull Defects.**—Lewin and his co-workers describe the use of tantalum for repair of traumatic skull defects at the Military Hospital for Head Injuries in Oxford and the immediate and late results of the first 128 cases followed up for a period of at least two years. Of the 124 cases traced 94 have been completely satisfactory and without complications two years or more following operation. Eleven of the 130 plates inserted have been removed, 5 on account of infection and 4 for an intracerebral complication; 2 were cosmetic failures. There were no postoperative deaths and the convalescence was usually uneventful, but in most patients serosanguineous fluid collected beneath the scalp and required aspiration. In 3 cases a subgaleal collection of cerebrospinal fluid persisted for several weeks. There was 1 case of postoperative wound infection. The cosmetic results were generally good. The incidence of infection, both early and late, was 7 per cent. There was no evidence that cranioplasty with tantalum diminished traumatic epilepsy. On the other hand, the operation may precipitate an attack. This occurred in 20 per cent of the epileptic group. For this reason all patients should be given anticonvulsants during the operative period. Plating may be successfully carried out three months after wounding or after healing of an infected wound. There is a possibility that tantalum in contact with the ventricular system may stimulate the production of cerebrospinal fluid. For these reasons the dural cover beneath the plate should be complete; all tears should be sutured or repaired with a fascia lata or pericranial graft. Tantalum is a satisfactory material for cranioplasty of the vault; its main disadvantage is that it is radio-opaque, and it would not be indicated in those cases in which it was thought that air studies might be required in the future. The authors gained the impression that in the low frontal region tantalum is probably not the repair material of choice, since the cosmetic result cannot be guaranteed with a one stage procedure, and the plates tend to slip unless special precautions are taken.

Gynatresia: Report of Three Uncommon Clinical Types. R. G. Maliphant.—p. 555.

**Lowered Incidence of Sensitization Through Use of Sulfonamide Combinations.**—On perusal of the extensive literature on sulfonamide compounds Lehr gained the impression that in the dosage range employed in human prophylaxis and therapy the incidence of drug rash and drug fever increases in direct proportion with the dosage of absorbable sulfonamide compounds. At an oral dosage of not more than 2 Gm. of sulfonamide drug in twenty-four hours none of the compounds used at present appears to produce rash or fever in any significant percentage of cases even if used for prolonged periods and repeatedly in the same persons. The incidence of these reactions assumes significant proportions when the dosage is increased to more than 4 Gm. in twenty-four hours, and reaches even higher percentages with full therapeutic amounts of 6 Gm. or more in twenty-four hours, provided medication is maintained for a minimum of three to five days. These observations indicate that the production of sensitization reactions is dependent on the repeated presence of certain critical tissue concentrations of a sulfonamide compound for several days. In the majority of patients sensitization is limited to the sulfonamide drug used for therapy. Hence the simultaneous administration of several sulfonamide drugs in partial dosage should result in a reduced incidence of sensitization because it permits "dilution" of individual drug concentrations below the level necessary for the production of allergy. Practical experience with combinations of two or three sulfonamide drugs in 610 patients demonstrated a conspicuously low incidence of drug rash and fever at the full therapeutic dosage of 6 Gm. in twenty-four hours. The author discusses the significance of this finding and its possible bearing on toxic reactions from compounds of the thiouracil series, and drug allergy in general.

**Streptomycin in Nontuberculous Infections.**—Wilson says that in December 1946 the Medical Research Council appointed a committee to arrange clinical trials of streptomycin in nontuberculous infections. The trials were extended to eleven centers. This report summarizes the pooled results of the investigation. Of the patients with meningitis who were treated with streptomycin 43 had the form caused by Hemophilus influenzae. From this series it appears that streptomycin alone is probably as effective in meningitis due to H. influenzae as any other form of treatment at present available. Because of the development of resistance an attempt was made to use a combination of streptomycin, penicillin and the sulfonamide compounds. In the other 14 patients with meningitis, the causative organisms included Escherichia coli, Pseudomonas pyocyanea, Staphylococcus pyogenes, Proteus, and Streptococcus faecalis. The infection was controlled in 11 instances. Streptomycin is a valuable therapeutic agent in pyogenic meningitis due to penicillin-resistant organisms. Five cases of subacute bacterial endocarditis due to Streptococcus viridans or H. influenzae and 1 case of uncertain nature have been treated. With the exception of the latter, the response to streptomycin has been only temporary. Two cases of septicemia without endocarditis due to Ps. pyocyanea or Esch. coli have responded satisfactorily. A series of 61 patients with infection of the urinary tract due to Esch. coli, Ps. pyocyanea, Proteus, Staph. pyogenes and Str.

faecalis has been investigated. In roughly half the cases the infection has been controlled by intramuscular administration of 3 Gm. of streptomycin daily for one to three days. Failure has almost always been due to the development of resistance. Fifty-five patients with local infections have been treated. These include infected burns, operation wounds, superficial ulcers, sinuses, abscess cavities and septic skin conditions. The results are favorable, particularly in superficial lesions. Chronic lung infections due to bronchiectasis and lung abscess (14 cases) have been treated. Although a temporary reduction in bacterial content of the sputum has been noted, there was little if any clinical improvement. Forty-two cases of infantile diarrhea have been treated by oral administration of 2 to 4 Gm. of streptomycin spread over seven days. So far treatment has not been sufficiently controlled to warrant definite conclusions. A small number of cases of ulcerative colitis and of typhoid have been treated with negative results.

## Acta Cardiologica, Brussels

### **3:**175-272 (No. 3) 1948

*Efficacy of Stellectomy in Angina Pectoris. Causes of Errors in Appreciation of Results. D. Danielopolu.—p. 175.
Reading of Left Ventricular Teleroentgenkymogram. R. Heim de Balsac.—p. 189.
Attempt of Roentgenologic Determination of Length of Ligamentum Arteriosum and of Arterial Canal. E. Donzelot and R. Heim de Balsac.—p. 212.

**Stellectomy in Angina Pectoris.**—According to Danielopolu it is erroneous to think that the anginal attack consists exclusively of pain, which presents only one of two constitutional elements of the attack. The motor element is the other element which changes the fundamental properties of the myocardium and which may be responsible for the cardiac arrest. The myocardium is the point of departure of the vicious pressor circle which produces the attack. The coronary constriction is the primary and the only essential phenomenon. The author's method for surgical treatment of angina pectoris aims to suppress the pressor reflex and consists of cutting the cervical sympathetic cord above the stellate ganglion, the cardiac branches of the cervical vagus and of the cervical sympathetic nerve, the vertebral nerve and the rami communicantes which unite the stellate ganglion with the fifth, sixth, seventh and eighth cervical and the first thoracic roots. The paths of the coronary-dilator reflex are not affected. By this method the endocardoaortic sensory filaments and the centrifugal parasympathetic filaments are intercepted and consequently the paths of the coronary-constrictor reflex are interrupted. The paths which conduct the thoracobrachial pain remain intact. The stellectomy suppresses the anginal pain, but does not prevent the attacks which continue, while the pain may be experienced only in the cutaneous areas where the sensory filaments which irradiate the pain have not been intercepted. The stellectomy does not suppress the motor element of the anginal attack; the attack may be produced, but not realized by the patient, and sudden death, myocardial infarct or congestive heart failure may result. The attack may be prevented by the author's physiologic method. It is masked by stellectomy, depriving the patient of the "signal of danger" which may induce him to avoid exertion.

Modification of Functional Disturbance of Liver of Nurslings by Cortex of Suprarenals. L. Barta.—p. 158.
Cold Injuries in Subtropical Climate. E. Nassau.—p. 167.

**Hookworm Anemia.**—Stransky and Dauis-Lawas point out that anemia due to iron deficiency is prevalent in the Philippines probably as the result of the dietary habits of the people, who live mostly on rice, dried fish and a few vegetables. The red blood cell count and hemoglobin level of the average Filipino are definitely lower than those of the average American. If there is hookworm infestation the low iron intake is insufficient to maintain a reasonable hemoglobin level and severe anemia develops. The war with its mass starvation and deterioration of living and hygienic conditions resulted in a great increase in hookworm anemia. This made it possible for the authors to study several aspects of hookworm anemia not investigated in their previous studies. Fourteen of their 15 patients were children; the fifteenth was a 20 year old mother, admitted with her 2 month old infant. Mother and child were severely anemic. This provided a chance to study the effect of maternal hookworm disease on the offspring. Blood, bone marrow and feces were examined. Hookworm anemia is usually microcytic and hypochromic, but macrocytosis is not exceptional. Fourteen of the 15 patients had anemia of the regenerative type, while 1 patient had aplastic anemia (panmyelophthisis). Loss of blood resulting from infestation with a blood-sucking insect is an important factor in the causation. Additional factors are iron, protein and vitamin deficiencies, and also secondary infections. Case histories indicate that if sufficient amounts of iron and protein are administered, the improvement is fast. Secondary infections delay the improvement. Commenting on the case of the young mother and her infant, the authors say that the anemia in the infant is due to lack of sufficient iron storage during fetal life on account of iron deficiency of the mother.

*Myelogram in Recently Acquired Syphilis. L. Bertellotti and E. Biagini.—p. 13.

**Myelogram in Syphilis.**—Bertellotti and Biagini studied myelograms of 30 patients with either primary or secondary syphilis. The material was obtained by sternal puncture. The majority of the patients were between the ages of 20 and 30 years. The myelogram was normal in all patients who were in good general condition, whereas it showed parenchymal hyperplasia in patients in poor general condition. The functional study of the sternal marrow showed a defect in the maturation of the cells, which in some cases was inhibited and in other cases accelerated. The curves of maturation did not follow typical diagrams. Hypereosinophilia was frequent in myelograms of patients who had had no treatment, as well as in those taken from patients in the course of Herxheimer reaction, of erythema of the ninth day, and of arsenical erythrodermia. The authors believe that Herxheimer reaction, erythema and erythroderma are allergic reactions to syphilis, treponema toxins and arsenic, respectively.

*Duodenal Ulcer in Child of Two Years: Case Report. Shao-Chow Pan and Yin-Tang Hsu.—p. 274.
*Nephritis in Scabies. K. C. Wang, C. T. Teng, C. C. Chen and C. K. Hu.—p. 277.
Urethral Diverticulum Complicating Neisserian Infection: Case Report. Yung-Yao Liu.—p. 280.

**Duodenal Ulcer in Child of Two Years.**—Pan and Hsu report the case of a boy, aged 2, who was hospitalized on Nov. 7, 1939. On October 31 the child exhibited a slight fever; he became irritable on the following day and drowsy on the third day. The child had one bowel movement every day, the stools being yellowish and soft in the first four days after onset but becoming dark on the fifth day. Five hours prior to admission he passed a tarry stool mixed with fresh blood. The boy died four days after hospitalization, after having passed more fresh blood and tarry stools and after vomiting coffee ground dermatologists find that treatment with vitamin A does appear to be somewhat helpful in an occasional case, but not in most cases. It is not a panacea. It has not replaced such measures as the intelligent and skilful use of (*a*) roentgen therapy, ultraviolet rays, or the so-called cryotherapy supplemented by (*b*) restriction of iodides, bromides and foods rich in fats; (*c*) the topical use of astringent and antiseptic lotions and, when indicated (*d*) the administration of estrogenic substances, and (*e*) attention to such factors as anemia, constipation, foci of infection and sedentary habits.

## CHLORINATION EFFECT ON POLIOMYELITIS VIRUS

*To the Editor:*—Does the usual method of chlorinating water render it safe for domestic use when there is known contamination by poliomyelitis virus? Is the study of this subject by Ridenour and Ingols, *American Journal of Public Health, June 1946, page 639,* authentic and conclusive? Has there been any correlation in areas having chlorinated domestic water and those having low incidence of poliomyelitis?

Harold F. Holsinger, M.D., Wendell, Idaho.

ANSWER. — There appears to be no reason for questioning the data reported by the authors cited. A later paper (Lense, Rhian and Stebbins, *Am. J. Pub. Health.* **37**:869, 1947) indicates that rise of $p_H$ reduces somewhat the virucidal action of free chlorine and discusses the relative effectiveness of free chlorine compared to that of chloramine. The only criterion available for inactivation of the virus is the result of inoculating susceptible animals. Conceivably, occasional persons might be infected by a dilution of virus too high to be detected by such a test, but evidence on this is lacking. Nearly all studies on chlorination have thus far been done with a single strain of virus (Lansing) because it is infectious to mice and therefore convenient to study. There are other strains for which the only available test animal would be the monkey. Inactivation of these strains by chlorine has not been adequately studied.

Statistical evidence of any relation between chlorination of local water supplies and incidence of poliomyelitis is not available.

## CHRONIC VAGINITIS

*To the Editor:*—A 24 year old married woman has had a vaginal discharge for six years. Vaginal examination reveals a thickened boggy intact vaginal mucous membrane covered with a dry gray-white discharge which has a $p_H$ of 6.5. The vaginal flora contains an organism tentatively identified as Acrobacter aerogenes. The urine on each of three tests was found to be swarming with bacteria. Urine culture was reported as positive for A. aerogenes. No other findings were made. Please advise additional diagnostic and therapeutic procedures.

W. R. Metzger, M.D., Corpus Christi, Tex.

ANSWER.—No mention is made of a hanging drop examination of the vaginal discharge. If this has not been done, a drop of vaginal secretion should be diluted with a drop of isotonic sodium chloride solution and examined under a dry high power lens. If Trichomonas vaginalis or Monilia organisms are present, they can readily be detected in the fresh hanging drop. A Monilia infection is often the cause of a grayish white discharge, but nearly always there is associated pruritus.

A useful drug for treatment of A. aerogenes infection is calcium mandelate. If this treatment does not bring about the disappearance of these bacteria, streptomycin should be used. The two forms of treatment may be used simultaneously.

## RETINITIS PIGMENTOSA

*To the Editor:*—1. Information is requested concerning studies carried out that may have confirmed the work of V. P. Filatov and V. A. Verbitska, "Treatment of Retinitis Pigmentosa with Intramuscular Injections of Cod Liver Oil" (*Am. Rev. Soviet Med.* **3**:388 [June] 1946).

Have the claims of A. Lipkina, "Tissue Therapy of Retinitis Pigmentosa (*Oftal. zhur.* no. 2, p. 29, 1946) been sustained?

Colonel, M.C., U. S. A.

ANSWER.—1. Dr. Dan M. Gordon and his colleagues at Cornell University College of Medicine have made an extensive study of retinitis pigmentosa treated by the method of Filatov and Verbitska. Results of this work, reported at the 1947 meeting of the American Academy of Ophthalmology and Otolaryngology and in the *American Journal of Ophthalmology* (**30**:565-580 [May] 1947) were disappointing and did not support claims of the Russian authors. In the May 1947 issue of the *American Journal of Ophthalmology,* page 635, will be found a critical editorial on the same subject.

2. Special work has not been done on the Lipkina method of treating retinitis pigmentosa with injections of aqueous extract of leaves of aloe conserved in the dark or of injections of this substance combined with implantation of conserved cadaver skin. Competent ophthalmologists in the United States believe that tissue therapy of retinitis pigmentosa is fruitless.

## ACUTE LYMPHATIC LEUKEMIA

*To the Editor:*—I have a nephew aged 17 years and weighing 165 pounds (74.8 Kg.). He had pneumonia and pleural effusion on the left side in August 1948 and was treated with penicillin and streptomycin. Blood cell count at that time showed 17,500 white cells with 65 per cent lymphocytes and 27 per cent polymorphonuclear cells. A cervical node was removed for study, and the pathologist made a diagnosis of acute lymphatic leukemia. He was given a transfusion and some roentgen treatment; yet his cell count still climbs. On September 17 his white cell count was 180,000. All of his lymph nodes have become enlarged. Can anything be done to relieve this boy? Would blood from one who had had the disease be of any benefit?

C. W. Durham, M.D., Greensboro, N. C.

ANSWER.—The diagnosis of leukemia cannot be seriously questioned in view of the white cell count and biopsy. If it is acute leukemia with a fulminating course and a high percentage (50 per cent or more) of blast forms there is no effective treatment. Even transfusions have little or no effect. The chronic forms of leukemia, on the other hand, with a relatively low percentage (10 per cent or less) of blast forms, are symptomatically improved by roentgen rays and various radioactive isotopes. It is doubtful whether life is actually prolonged, however. Transfusion with blood from other persons who had had leukemia is not known to be of benefit.

## ACHONDROPLASTIC DWARFISM

*To the Editor:*—What are the chances of a second achondroplastic dwarf's being born to the same apparently normal parents? What treatment can be expected to cause an achondroplastic dwarf of 10 months to approximate normal?

Albert W. Holman, M.D., Portland, Ore.

ANSWER.—Statistics are not available to indicate either the frequency with which achondroplastic dwarfism appears in the population or the chance that more than one infant will be born to the same parents. The condition may be hereditary in occurrence. The hereditary tendency for the condition to occur has demonstrated itself in (1) father and daughter; (2) grandfather, father, brother and sons, and (3) twins. It has been observed three times in brothers and sisters.

An achondroplastic parent of either sex may have normal children, which is the usual occurrence. The female is more predisposed to the condition than is the male. Readers are referred to the monograph by Rischbeith and Barrington in "The Treasury of Human Inheritance" (London, Dulau and Company, Ltd., 1912, vol. 1, pts. 7-8, p. 355), which presents eighty genealogic tables of families in which achondroplastic dwarfism has occurred.

Treatment of value in influencing the nature or the rate of growth of persons suffering from achondroplastic dwarfism is unknown.

## ANOMALY OF UTERUS

*To the Editor:*—What is the frequency of (1) congenital small uterus with single tube and ovary, and (2) parametrial fibroids?

H. Ostry, M.D., Calgary, Alberta, Canada.

ANSWER.—1. It is assumed that "the congenital small uterus" is meant to be truly an undeveloped uterus which is sometimes called a juvenile uterus. The müllerian system is a double system, and uterus, fallopian tubes and upper part of the vagina develop from it. Only one side may proceed to development, but a thorough dissection and examination should reveal remnants, macroscopically or miscroscopically, of the original structure. Likewise the gonads are bilateral and should develop accordingly; possibly only one may reach a recognizable size. Clinically there may appear to be but one horn of the uterus and perhaps but one tube and ovary in association with it. Such abnormalities are extremely rare. Consequently, percentages are insignificantly low.

2. Parametrial fibroid refers to extension or growth of the fibroid outward into the leaves of the broad ligament. This occurs not uncommonly but is less frequent than the classical intramural and subserous fibroid. Liomyomas or fibroids are usually multiple, and the interligamentous types vary in degree. Perhaps for these reasons the authors of several texts do not give percentages of this type.

## INTRAVENOUS ADMINISTRATION OF ETHER

*To the Editor:*—Please evaluate intravenous administration of ether in treatment of arteriosclerosis.

M.D., Michigan.

ANSWER.—Ether administered intravenously has no lasting curative or preventive value in the management of arteriosclerosis. Minute doses may induce temporary relief of some of the acute transient manifestations.

# DIAGNOSIS OF CARCINOMA OF THE LUNG

## The Value of Cytologic Study of Sputum and Bronchial Secretions

LEWIS B. WOOLNER, M.D.
and
JOHN R. McDONALD, M.D.
Rochester, Minn.

The cytologic examination of sputum and bronchial secretions has proved to be an extremely valuable adjunct in the diagnosis of carcinoma of the lung. The practical value of the method was first demonstrated by Dudgeon and Wrigley[1] in 1935. Their method consisted essentially in making films of fresh sputum, fixing, while wet, in Schaudinn's solution and staining with hematoxylin and eosin. Subsequent studies by Barrett,[2] Gowar[3] and especially the thorough investigation of the subject by Wandall[4] served to reemphasize the importance of a painstaking cytologic examination of sputum as an important link in the examination of patients believed to be suffering from primary bronchogenic carcinoma.

A study of bronchoscopically removed secretions was advocated by Herbut and Clerf,[5] who felt that bronchial secretions are superior to sputum as a source of carcinoma cells. The method of fixation and the staining technic used were those advocated by Papanicolaou.[6]

The smear technic as a basis for diagnosis of malignant neoplasm having a free surface has been advocated for many years by Papanicolaou.[7] He has reported the results of sputum examination as positive in 88 per cent of 25 proved cases of carcinoma of the lung.[8] Of 25 cases in which the results were reported negative on the basis of smears, in 3 malignant neoplasms were eventually shown to be present, in 1 the diagnosis remained obscure and in 21 (84 per cent) the final diagnosis was something other than malignant disease.

Our experience with cytologic examination of sputum and bronchial secretions has served to convince us of its tremendous practical value in the diagnosis of indeterminate pulmonary lesions. The technic used and a discussion of the characteristics of exfoliated carcinoma cells in sputum or secretions have been outlined in previous reports by us.[9] To date we have examined the sputum or bronchial secretions of 2,188 patients. All material was examined as "unknowns" and reported positive or negative for carcinoma cells. In doubtful cases additional specimens were called for. A diagnosis of carcinoma on the basis of smears was given in a total of 200 cases. Pertinent data on these 200 cases in which the sputum or bronchial secretions were reported positive for carcinoma cells were then collected. The diagnostic value of the method and the accuracy of the diagnosis, particularly in regard to false positive reports, were determined from a study of these cases.

The accuracy of the diagnosis in the 200 cases in which a diagnosis of carcinoma was made on the basis of the examination of smears is of interest. In 121 cases a diagnosis of bronchogenic carcinoma was established on the basis of tissue sections obtained by bronchoscopic biopsy, surgical exploration, biopsy of lymph nodes or autopsy. In 69 cases a final clinical diagnosis of bronchogenic carcinoma or metastatic carcinoma was made. This was based on clinical and roentgenologic findings, evidence of metastasis and so forth. All lesions were considered inoperable on surgical consultation. In 4 cases, carcinoma was demonstrated in the larynx, trachea or esophagus. In 4 cases proved not to be carcinoma a false positive report was given. In 2 additional cases, whether the lesion was inflammatory or neoplastic remained doubtful.

### ANALYSIS OF CASES

*Cases in Which Surgical Exploration Was Performed.*—In this series, 74 patients with bronchogenic carcinoma underwent surgical exploration. Twenty-nine, 40 per cent of these patients, had exfoliated carcinoma cells in the sputum or bronchial secretions as the sole preoperative microscopic evidence of cancer. The diagnosis was based on sputum examination in 18 cases, on examination of bronchial secretions in 6 cases, on examination of both secretions and sputum in 3 cases

---

and on examination of bronchial washings or smears (direct swabbing of the bronchial wall) in 1 case each. In our experience sputum and bronchial secretions have proved equally satisfactory in the cytologic diagnosis of cancer of the lung. Bronchial secretions have the advantage of better localization of the lesion, while sputum is more readily obtainable and additional specimens can be obtained readily if necessary. If the patient does not have sputum and if no bronchial secretions can be aspirated, an occasional diagnosis is made on the basis of bronchial washings, that is, by instilling isotonic sodium chloride solution into the affected bronchus, with subsequent aspiration. In a few cases smears made by direct swabbing of the bronchial wall provided microscopic evidence of the presence of carcinoma.

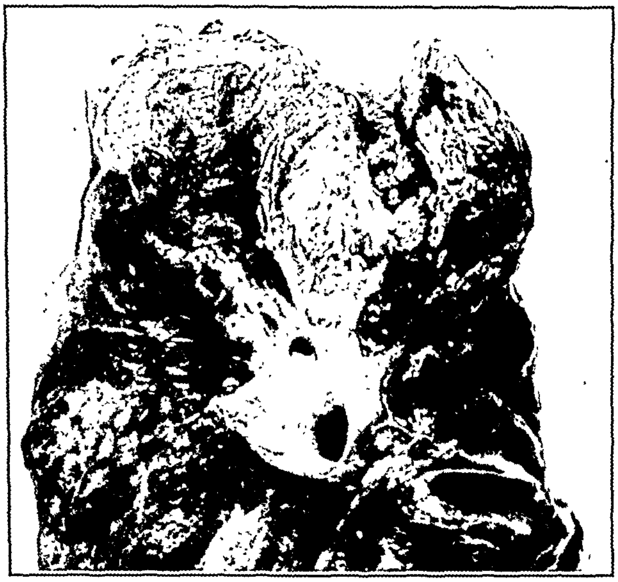

Fig. 1.—Bronchogenic carcinoma of the upper lobe surgically removed on the basis of exfoliated cancer cells in the sputum.

The majority of inaccessible bronchogenic carcinomas occur in relation to the bronchi of the upper lobes. In 12 of the 29 cases in which exploration was done on the basis of findings in smears, the carcinoma arose from the bronchus to the upper lobe of the left lung bronchus and in 6 cases from the bronchus to the upper lobe of the right lung. The lower lobe of the right lung, lower lobe of the left lung and middle lobe of the right lung were involved in 2 cases each. In 3 cases, the location of the tumor was at the orifice of the bronchus to the upper lobe of the left lung and the adjacent main bronchus. In 2 cases, the bronchus to the lower lobe of the right lung and the adjacent right main bronchus were involved.

In all the 29 cases, except 1, bronchoscopic examination was carried out. In 13 cases the bronchoscopic report read "completely negative" or "unable to find any tumor in the bronchial tree." In 3 cases deformity or stenosis of a bronchus tc an upper lobe was noted. Pus arising from the bronchi to the upper and the middle lobe of the right lung suggested an inflammatory process in 1 case. A mass obstructing the bronchus to the middle lobe of the right lung was present in 1 instance. In 1 case in which a large cystic lesion in the upper lobe of the left lung was shown roentgenologically, no bronchoscopic examination was performed. In the remaining 9 cases, infiltration about, or a degree of fixation of, the bronchus was reported as suggestive of malignancy. The results of bronchoscopic biopsy in all these cases, however, were negative for carcinoma.

In all the 29 cases but 1, roentgenologic shadow in the lung provided evidence for localization of the lesion. In the 1 case in which no mass was demonstrable on routinely made roentgenograms, a tomogram revealed an irregularity of the bronchus to the upper lobe of the left lung. In 2 cases the roentgenologic appearances were more suggestive of tuberculosis than neoplasm. In 1 case the roentgenologic report was "abscess or cavitating carcinoma," in 1 thickened pleura with residual fibrosis, and in 1 the appearances suggested bronchiectasis.

In 1 additional case proved by bronchoscopic biopsy and not included in this group, the results of sputum examination were positive for carcinoma cells but no evidence of carcinoma was found in the roentgenograms. Bronchoscopic examination revealed a squamous cell carcinoma of the right main bronchus near the carina which involved the lower end of the trachea.

*Pulmonary Resection for Bronchogenic Carcinoma on the Basis of Findings in Smears.*—In 13 of the 29 patients with bronchogenic carcinoma who had exfoliated carcinoma cells in the sputum or bronchial secretions and who underwent surgical exploration, the lesion was removable surgically. A preoperative diagnosis of bronchogenic carcinoma was made in all 13 cases on the basis of the cytologic features of the smears of sputum or bronchial secretions. In figures 1 and 2 are shown the gross appearance and the exfoliated cancer cells in the sputum in the case of one of these surgically removed bronchogenic carcinomas. The lesion was situated in the upper lobe of the left lung in 8 cases, in the upper lobe of the right lung in 1 case, in the middle lobe of the right lung in 1 case and in the lower lobe of the left lung in 3 cases. In 8 cases

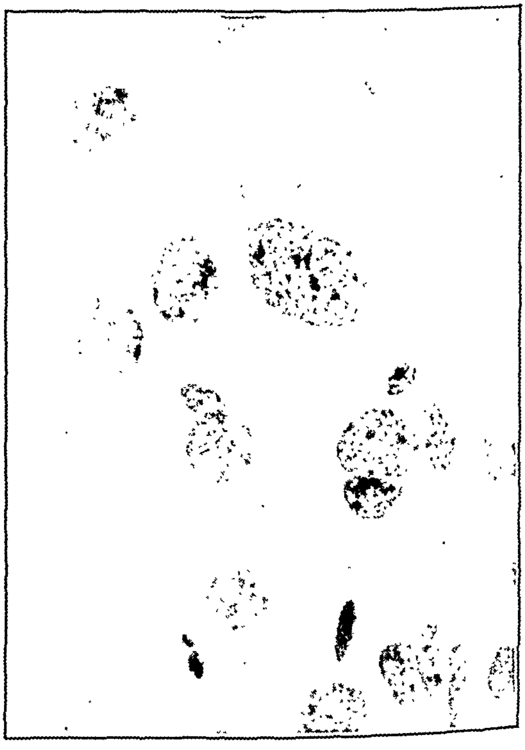

Fig. 2 (same case as fig. 1).—Bronchogenic carcinoma of the upper lobe. Exfoliated cancer cells in sputum (hematoxylin and eosin × 750).

the results of bronchoscopic examination were reported as "completely negative." In 1 case bronchoscopic examination was not carried out. In 4 cases, the appearance of the lesion, infiltration or fixation of the bronchus suggested carcinoma to the bronchoscopist but the results of biopsy were negative.

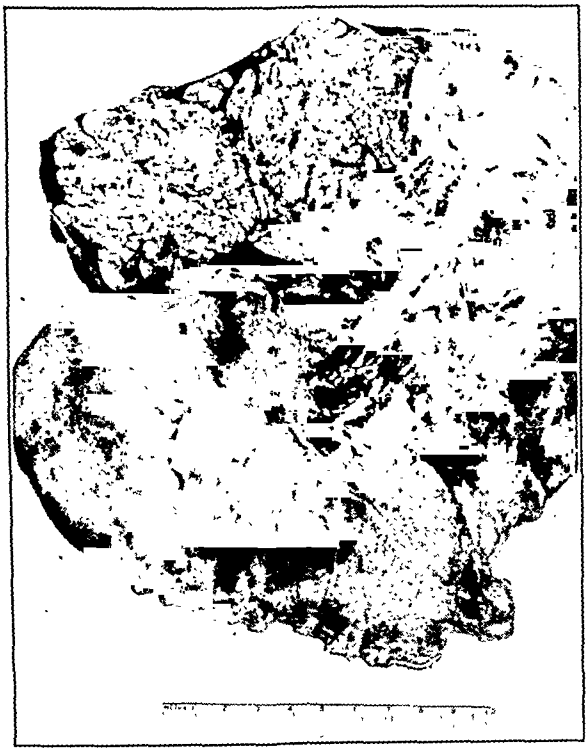

Fig. 3.—Superior sulcus tumor removed surgically.

In 3 cases the clinical picture was atypical. One of the patients in these 3 cases, who was subject to "chest colds" each winter, complained only of a cough which this time had failed to clear up as was usual after the cold weather. Bronchoscopic examination gave negative results and the roentgenogram was reported as showing thickened pleura with residual fibrosis in the base of the right lung. The presence of exfoliated cancer cells in the sputum, however, established the diagnosis of carcinoma, and resection was carried out. The other 2 cases are of sufficient interest to report in some detail.

Case 1.—A 39 year old man had rather acute symptoms for one month. These included fever, malaise, night sweats and some loss of weight. Symptoms relating to the thorax were minimal, and included pain in the left axilla and slight hemoptysis for two days before admission. Physical examination gave essentially negative results. Roentgenograms of the thorax revealed a "pathologic process left apex and first anterior interspace. There is considerable pleural reaction which is probably tuberculosis but primary malignancy cannot be ruled out." A bronchoscopic examination was carried out but no evidence of tumor could be seen. The sputum was negative for acid-fast bacilli and fungi. Clinically the picture did not suggest cancer but rather favored an infectious process. Skin tests were positive for Brucella as was the serum agglutination in a dilution of 1:400. No organisms could be isolated by blood culture. The diagnosis was established by a cytologic examination of sputum, in which were found numerous exfoliated cancer cells. On the basis of the carcinoma cells in the sputum and the localization of the lesion by roentgenogram, a left pneumonectomy was carried out. A highly undifferentiated bronchogenic carcinoma measuring 2 cm. in diameter was found in the left apex. The tumor involved a small bronchus 5.5 cm. distal to the orifice of the bronchus to the upper lobe of the left lung. No lymph nodes were found involved. The patient made an uneventful recovery and was dismissed in good condition.

Case 2.—A man aged 63 years consulted his doctor in his home community because of a "sensation" under the sternum that had been present off and on for two years. He was told he had an "enlarged artery" leading from his heart. He was in good health and had no other symptoms. Two months before admission he had had a slight cold and cough lasting two to three days, but these had cleared up completely. Examination of his chest gave essentially negative results, as did the remainder of the physical examination.

Roentgenographic and roentgenoscopic examination of the thorax at the clinic revealed a decided torsion of the aorta. No definite tumor could be demonstrated in the left hilus.

A sputum examination done at this time revealed carcinoma cells. Bronchoscopic examination was carried out and the results were negative. The results of two subsequent sputum examinations were reported as negative. Because of the absence of symptoms of carcinoma and the failure to locate a mass roentgenologically the possibility of error in interpretation of the sputum smears was considered. However, carcinoma cells were found in a second specimen of sputum and tomographic studies were carried out. The tomogram showed a "mass just above the left main bronchus which is probably an infiltrating bronchogenic carcinoma." On the basis of the carcinoma cells in the sputum and localization by tomograms a left pneumonectomy was carried out. Pathologic examination revealed a squamous cell carcinoma only 2 cm. in diameter involving the anterior inferior branch of the bronchus to the upper lobe. One hilar lymph node was found involved.

These 2 cases show the value of routine examination of sputum in cases of indeterminate thoracic lesions. In both, symptoms were lacking or atypical. Both lesions were inaccessible to bronchoscopic biopsy. In neither case could a definite diagnosis of bronchogenic carcinoma be made on routinely made roentgenograms of the chest.

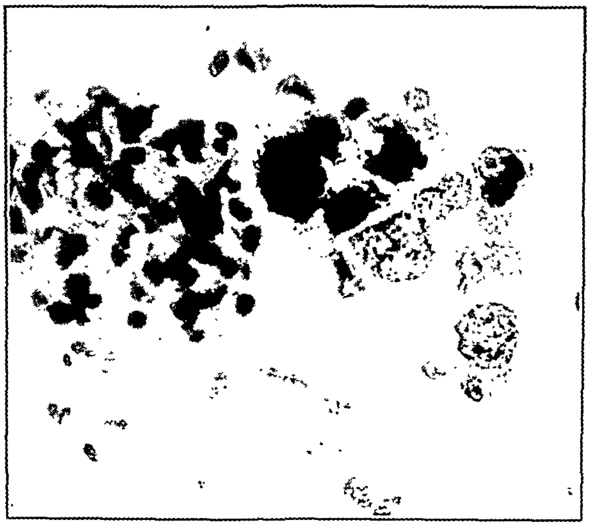

Fig. 4. (same case as in fig. 3)—Carcinoma cells found in the sputum (hematoxylin and eosin × 750).

*Pancoast's Superior Sulcus Tumor.*—Tumors of the pulmonary apex or superior sulcus tumors constitute a highly inaccessible group of neoplasms. Proof of the condition is frequently lacking until a late inoperable stage has been reached, the diagnosis depending frequently on finding destruction of adjacent bony tissue or the presence of Horner's syndrome. Cytologic examination of sputum and bronchial secretions serves as a valuable diagnostic aid in detecting such neoplasms and in establishing a diagnosis without delay.

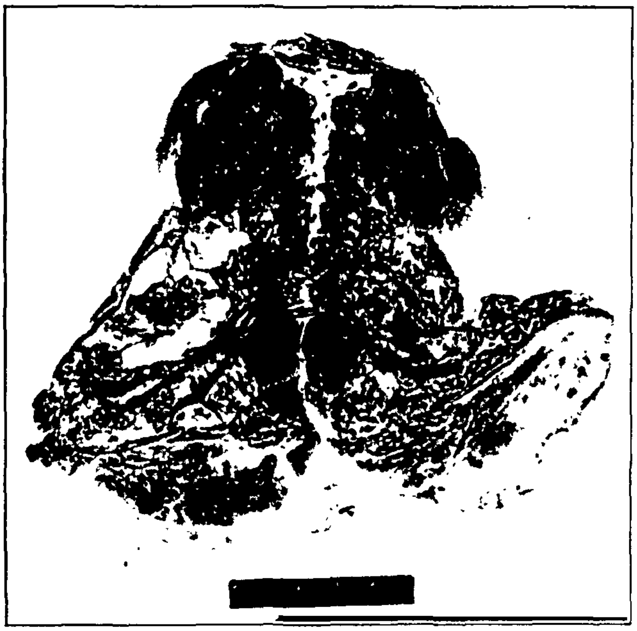

Fig. 5.—Alveolar cell tumor of the lower lobe of the left lung.

In this group of cases, 6 superior sulcus tumors were diagnosed on the basis of the position of the roentgenologic shadow and the presence of positive cytologic evidence. In 5 of these cases, the sputum was positive for carcinoma cells; in the sixth case no sputum or bronchial secretions could be obtained and the diagnosis was established by finding cancer cells in the bronchial washings. The tumor was situated in the right apex in 3 cases and in the left apex in 3 cases.

Bronchoscopic examination was carried out in 2 cases and gave negative results in both. Pneumonectomy was performed in these 2 cases. In 1 a small bronchogenic carcinoma 2 cm. in diameter was found in the apex of the lung directly under the pleura, but so far as could be determined the process was still confined to the pulmonary tissue. In the second case the tumor was freed with some difficulty from the apex of the thoracic cavity and brachial plexus and whether complete removal was effected was highly doubtful. The appearance of this tumor and of the carcinoma cells found in the sputum is shown in figure 3.

In the remaining 4 cases the lesions were inoperable. In 3 of the cases there was roentgenologic evidence of erosion of adjacent ribs or vertebrae. In the fourth case metastasis to the left ischium had occurred. The 3 patients who had inoperable lesions complained of severe pain in the shoulder girdle and arm, and in 1 of these Horner's syndrome was present.

It is interesting to note that the sputum may be positive for carcinoma cells even in this most peripherally located and inaccessible group of pulmonary tumors. Microscopic proof of the presence of carcinoma may be provided by this technic when all other methods fail. Since only a few carcinoma cells may be found in the sputum in some of these cases, several specimens should be examined if necessary before an indeterminate lesion is considered, on the basis of findings in smears, not to be a carcinoma.

*Alveolar Cell Tumor.*—In 4 cases in this series, carcinoma cells found in the sputum or bronchial secretions were believed to have arisen in an alveolar cell tumor of the lung. In the first case, the tumor involved the greater portion of the lower lobe of the left lung. Bronchoscopic examination revealed no tumor, but bronchial smears were found positive for carcinoma cells. The lobe was removed surgically. Histologically the tumor was a typical alveolar cell tumor. The appearance of the removed lobe, the carcinoma cells in the bronchial smears and the histologic section are shown in figures 5 and 6. In a second case, roentgenograms of the thorax revealed extensive bilateral dissemination of discrete nodular lesions. The sputum was positive for carcinoma cells. Biopsy of an enlarged left supraclavicular lymph node revealed a histologic picture compatible with that of a metastatic lesion from an alveolar cell carcinoma. In 2 additional cases, carcinoma cells were found in the sputum and the roentgenologic appearance of the pulmonary fields was consistent with that of alveolar cell carcinoma. No tissue section was obtained in either of these cases. Bronchoscopic examination was done in 1 case but no tumor was demonstrated in the bronchial tree. One patient died shortly after dismissal, but autopsy was not performed.

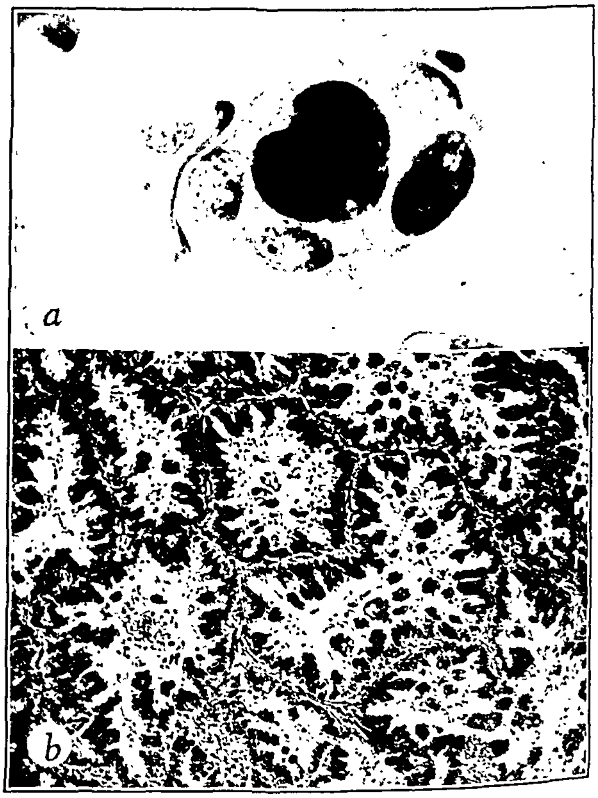

Fig. 6. (same case as fig. 5).—(*a*) Carcinoma cells in bronchial smears (hematoxylin and eosin × 750). Alveolar cell tumor of the lower lobe of the left lung. (*b*) tissue section (hematoxylin and eosin × 75).

*Adenoma and Cylindroma of the Bronchus.*—This group of tumors comprises about 10 per cent of primary pulmonary neoplasms. They arise from the submucous glands or their ducts, and the bronchial epithelium is usually intact over the surface. They form polypoid tumors that usually arise from one of the larger bronchi and are thus readily accessible to bronchoscopic biopsy. In our experience atypical cells are not found in the sputum or bronchial secretions in either the adenoma or cylindroma groups. This is not surprising in view of the well differentiated histologic pattern of the tumor and especially because of their covering of benign bronchial epithelium.

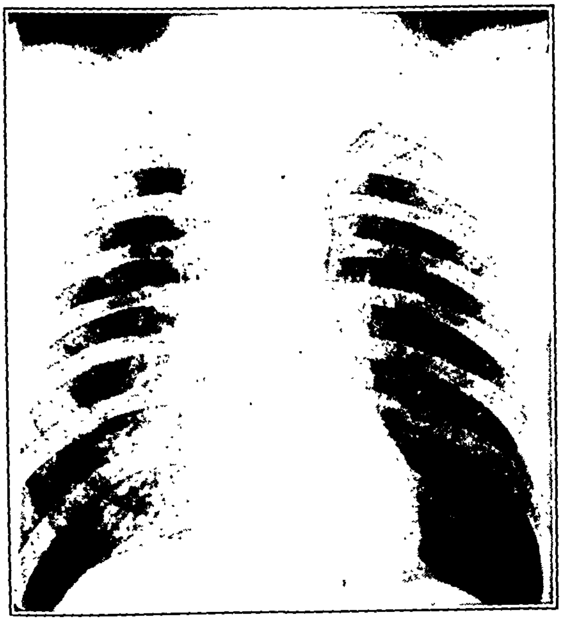

Fig. 7 (case 3).—Normal roentgenogram of the thorax.

*Diagnostic Value of Sputum Examination in Patients Who Do Not Undergo Bronchoscopy.*—In 43 cases in this series bronchoscopic examination was not carried out. In approximately one half of these cases there was roentgenologic or clinical evidence of metastasis. Demonstration of carcinoma cells in the sputum in these cases is largely an academic matter and serves merely to provide additional evidence of a primary bronchogenic neoplasm. In a certain number of cases, however, the patient cannot undergo bronchoscopy by reason of age, general physical condition or cardiac or cerebral disease. The presence of exfoliated cancer cells in the sputum in these cases provides a convenient method of confirming by microscopic means the clinical impression of bronchogenic carcinoma. The value of sputum examination in such instances is shown by a recent case encountered by us and not included in this series.

Case 3.—A man aged 42 years complained of a sensation of pressure in the head on coughing, straining or bending. The only other symptom was a cough that had been present for the past two and one-half months. Five years before admission he had had symptoms suggestive of a ruptured intracranial aneurysm following aerial acrobatics. Spinal tap at that time had revealed bloody fluid. No further cerebral symptoms had been noted in the meantime. On admission to the clinic he presented evidence of progressive obstruction of the superior vena cava. Studies revealed a venous pressure of 36.4 in the left brachial vein and 9.2 in the left saphenous vein, both expressed in centimeters of isotonic sodium chloride solution. Routine roentgenologic examination of the thorax gave negative results (fig. 7). Anteroposterior and lateral roentgenograms made with the aid of a Bucky diaphragm did not reveal any abnormality.

Examination of the sputum revealed large numbers of carcinoma cells (fig. 8). A diagnosis of bronchogenic carcinoma with invasion of the superior vena cava was made. Bronchoscopic examination was not considered advisable because of the history of a cerebral accident in 1943. An enlarged left axillary node was present, but biopsy was not considered necessary in view of the unequivocal sputum findings.

*False Positive Diagnoses by Smear Technic.*—In this series, 200 positive reports were given on the basis of examination of smears of sputum or bronchial secretions. Four of these positive reports were subsequently proved to be false. In 2 cases, lobectomy was carried out. In 1 a chronic tuberculous process was present in the upper lobe with stenosis of the upper lobe bronchus. In the other case, lobectomy revealed pronounced bronchiectasis. In 1 case in which smears were reported positive for carcinoma cells pneumonectomy revealed only chronic pneumonitis. In the fourth case in which a false positive report was made, autopsy revealed extensive infarction in addition to an organizing pneumonic process in both lungs. Examination of the mucosa of the large bronchi revealed portions in which there were squamous metaplasia and marked epithelial proliferation, mitotic figures being seen in the hyperplastic epithelial cells.

In 2 additional cases in which smears were reported positive for carcinoma cells the clinical impression was that of an inflammatory process. One of these patients presented roentgenologic evidence of extensive cavitation of the upper third of both pulmonary fields. Sputum studies were negative for acid-fast bacilli but showed numerous cells interpreted as carcinoma cells. Bronchoscopy failed to localize any malignant process. No follow-up data in this case were available. In the other case the final clinical diagnosis was empyema, and further information has not been obtained.

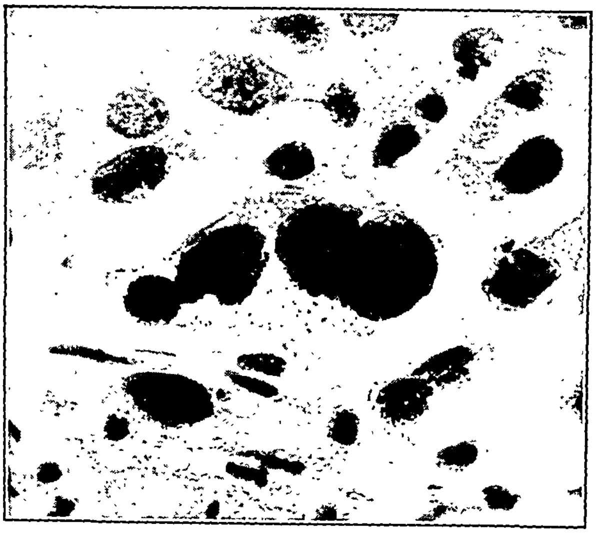

Fig. 8 (case 3).—Carcinoma cells found in the sputum (hematoxylin and eosin × 750). This patient presented evidence of obstruction of the superior vena cava.

The accuracy of diagnosis with this technic varies directly with the experience of the cytologist. Erroneous diagnoses may occur especially in the early period of investigation before sufficient experience has been acquired. After a large volume of work has been done, however, a remarkable degree of accuracy may be expected. When this degree of accuracy has been attained, the findings on sputum examination in the majority of cases of carcinoma are as convincing to the cytologist as are the findings on tissue section. Good judgment must be exercised in cases in which the cells are not markedly atypical or in which only a few suspicious cells are found. It is important that the smears be covered methodically so that a few isolated carcinoma cells do not escape notice. In doubtful cases additional smears should always be examined.

### SUMMARY AND CONCLUSIONS

An analysis of 200 cases in which a diagnosis of carcinoma was made on the basis of examination of smears of sputum or bronchial secretions has been carried out. In 190 cases a final diagnosis of bronchogenic carcinoma or pulmonary metastatic carcinoma was made. In 4 cases a carcinoma in the esophagus, larynx or trachea was demonstrated. In 4 cases the diagnosis was proved to be falsely positive. In the remaining 2 cases the final diagnosis was uncertain.

Exfoliated carcinoma cells in sputum or bronchial secretions provided the only preoperative microscopic evidence of cancer in 29 of 74 cases of bronchogenic carcinoma in which surgical exploration was carried out. In 13 cases of bronchogenic carcinoma in which the lesion proved removable, a preoperative diagnosis of cancer was based on the cytologic characteristics of sputum or bronchial secretions. In 6 cases of Pancoast's tumor and in 4 cases of alveolar cell tumor there were carcinoma cells in the sputum.

Cytologic examination of sputum is of great diagnostic value in the case of patients suspected of having bronchogenic carcinoma in whom bronchoscopic examination is contraindicated.

### ABSTRACT OF DISCUSSION

Dr. Henry A. Cromwell, New York: Dr. McDonald has presented representative slides of sputum and bronchial washing smears and has given an able discussion of the cytologic method of diagnosis of lung cancer. The internist must, however, be alert to the possible presence of lung cancer at all times. To diagnose lung cancer the clinician must first suspect its presence. A few of the questions which he must ask himself are: Is cancer lurking behind that lung abscess, this case of pneumonia, that case of atelectasis and pleural fluid, or is it the basis of that so-called tobacco cough? Can the patient's nervousness and loss of weight, sleeplessness and anorexia be due to an undiagnosed lung cancer? Has the patient with the infiltrative lesion in the upper lung field tuberculosis, as reported by the x-ray department, or is the lesion cancer of the lung? How are we going to find out? Are we going to take the roentgenologic report at face value? Because he has a negative bronchoscopy or bronchial biopsy, are we going to consider his lungs free of cancer? Are we going to have a sputum smear and because it is negative entertain no further ideas of cancer? No one method and no single report, positive or negative, for cancer should be accepted as final. A recheck is always in order. Most diagnoses are still made by the clinician who makes full use of all laboratory tests at his disposal. We are recommending a four to six month training course for pathologists who wish to undertake this method of diagnosis. It is hoped that these men not only will be able accurately to diagnose lung cancer by examination of sputum and bronchial washing smears but will become instructors for other pathologists who subsequently will desire to use this method.

# ARTERIOGRAPHY IN CEREBRAL VASCULAR ACCIDENTS

I. S. WECHSLER, M.D.
AND
S. W. GROSS, M.D.
New York

In a paper[1] read before the American Neurological Association in June of 1947, we reported our results with arteriography[2] in cases of acute and subacute subarachnoid hemorrhages due to intracranial aneurysms and other vascular malformations. Since our present investigation grew out of that work, it may be well to summarize our findings in 10 cases of spontaneous subarachnoid hemorrhages. In 6 the condition was due to vascular malformations and in 4 to aneurysms of the circle of Willis, in all demonstrated by arteriographic study. Ligation of the common carotid artery was done in nearly every case in which the arteriograms disclosed either a vascular malformation or an aneurysm. We have employed this procedure since 1941 and, with one exception, observed no ill effects. Since our earlier report was made, ligation of the common carotid was done in several more cases of acute subarachnoid hemorrhage due to aneurysms of the cerebral vessels.

Encouraged by the results of arteriography in cases of vascular anomalies, we began to use the method in instances of cerebral vascular accidents in order to learn whether the nature of the lesion could be determined with more certainty and whether surgical treatment could be instituted. Ordinarily, differentiation between hemorrhage, thrombosis and embolism is not difficult. There are, however, cases in which the usual criteria fail. The margin of error obviously varies with the clinician's experience and his diagnostic acumen, but, even so, all that can be done in many instances is to venture an opinion. In any case, all one tries to do is to make a diagnosis. One merely hopes for recovery. If it does not occur rapidly, invalidism of long duration, possibly permanent, is anticipated. Of treatment there is little. Should the physician, for example, want to give dicumarol® or heparin, whatever their value, it is clear that he must first be absolutely certain that he is dealing with a thrombosis, which is precisely what he cannot be. If he decides on trephinement, he must be sure that there is a hemorrhage and know where it is. It is our opinion that arteriographic study can help to distinguish between the two with a fair degree of accuracy and point to the exact location.

At first we felt our way slowly in the treatment of cerebral apoplexies, as we did in the treatment of subarachnoid hemorrhages, to learn which cases were suitable for arteriographic study, how to select them properly and, most important, how to determine the optimum time for such a study. But it is not merely diagnosis in which we were interested; this was merely the first step to rational treatment. If the diagnosis of hemorrhage is made, then we feel that trephinement is indicated and that the attempt to aspirate the blood or, if the arteriogram is made some time after the ictus, to evacuate the clot is justified. While we appre-

[2] Angiography includes both an arteriogram and a venogram.

ciate the theoretic arguments against the procedure, and similar ones were advanced against the use of arteriography in cases of acute subarachnoid hemorrhage, we can say with assurance that the procedure is safe and sometimes therapeutically valuable.

As our material is still limited, we can only venture a tentative opinion at this time. This report is based on 10 cases of cerebral vascular accidents in which arteriographic study was used. The following are a few typical case histories. Aspiration of blood or removal of a clot has led to rapid improvement in some patients who otherwise would have made little or no recovery. By operating on patients with hemorrhage, and we did not treat surgically those with thromboses, we may be able to prevent irreversible damage. While we cannot as yet say what the optimum time for an arteriogram and trephinement is, it is our growing conviction that the earlier it is done the better. If the patient's condition is not too poor, one may operate within a few days of the vascular accident. It seems to us that the shorter the waiting period the better, but it should not be more than a week or two. The blood or the clot, acting as a foreign body, destroys brain tissue, and if allowed to continue may bring about irreversible changes.

## REPORT OF CASES

Case 1.—A white man, aged 21, had been in good health except for the occurrence of rheumatic fever six years before. On the day of his admission to the hospital he awoke with a severe frontal headache. Within a few hours he became aphasic and vomited repeatedly. On examination he appeared acutely ill. His blood pressure was 120 systolic and 70 diastolic and the pulse rate 70. He had an expressive aphasia and, on the right side, hemiplegia, homonymous hemianopsia and hemisensory syndrome with astereognosis. The fundi were normal at this time. The spinal fluid was bloody under a pressure of 300 mm. The presumptive diagnosis was spontaneous subarachnoid hemorrhage. The patient remained severely ill for several days. Rigidity of the neck, fever, stupor and, within a few days, papilledema developed. An arteriogram (fig. 1) showed a pronounced elevation of the left sylvian vessels. Craniotomy disclosed a large intracerebral hematoma in the left temporo-occipital area. After removal of the hematoma the patient recovered completely and has remained well to date, about one year later. The cause of the intracerebral bleeding was not discovered. The rapid and ultimately complete recovery clearly was the result of the removal of the clot.

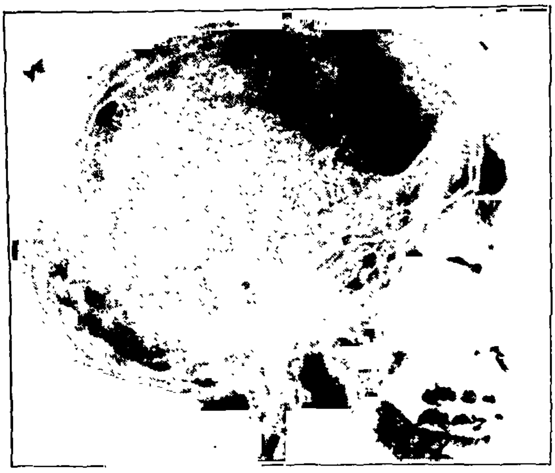

Fig. 1. (case 1).—Pronounced elevation of left sylvian vessels; hemorrhage.

Case 2.—Except for a head injury about one year previously, the patient, a 39 year old white man, had always been in good health. On the day of his admission to the hospital hemiplegia suddenly developed on the left side, followed by drowsiness and stupor. On examination there was rigidity of the neck, conjugate deviation to the eyes to the right and hemiplegia, homonymous hemianopsia and a hemisensory syndrome of the left side. The fundi showed early choked disks. The cerebrospinal fluid was grossly bloody under a pressure of 360 mm. He remained severely ill, with high fever, stiff neck and stupor. A few days later an arteriogram was done. This showed (fig. 2) a depression of the beginning of the sylvian vessels, with a straight vertical course of the ascending frontoparietal branches. At operation a moderately large subcortical hemorrhage in the posterior frontal and anterior parietal area near the sylvian fissure was found. The patient improved rapidly after evacuation of the intracerebral clot. The cause of bleeding in this case also was not determined. Again, the rapid recovery was due to surgical treatment.

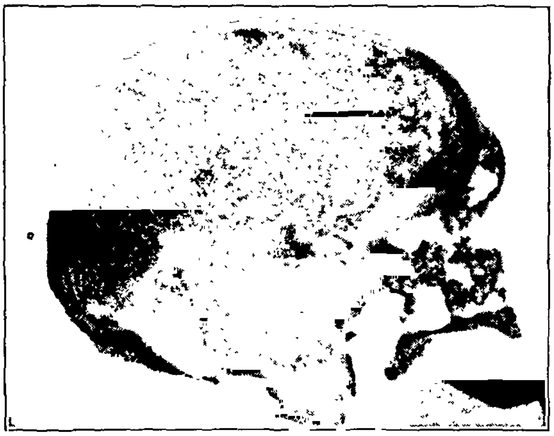

Fig. 2. (case 2).—Depression of beginning of the sylvian vessels. Vertical course of ascending frontoparietal branches; hemorrhage.

Case 3.—A white man, aged 50 and left handed, was seen in consultation with Dr. William A. Kelly of Mount Vernon. He was known to have hypertension. He had a sudden attack of hemiplegia on the left side and coma. On his admission to the hospital he was comatose and the blood pressure was 180 systolic and 120 diastolic and the pulse rate 80. Within a few hours he became conscious. The eyes deviated to the right, and he was completely aphasic and had hemiplegia. The cerebrospinal fluid obtained the next day was uniformly bloody. His condition remained stationary in that there was no recovery for twelve days. It was then that an arteriogram was done by Dr. Wingebach (fig. 3). This showed elevation of the sylvian group of vessels. At operation a subcortical hematoma about 12 cm. in diameter and 6 cm. below the surface was removed. The patient began to speak about two days later and has continued to improve.

Case 4.—A 44 year old white woman, right handed, suddenly experienced severe left frontal pain and blurring of vision at about 1 p. m. on May 13, 1947. This was followed several hours later by drowsiness, aphasia and hemiparesis on the right side. She was admitted two days later to the Mount Sinai Hospital in a lethargic condition. She had hemiplegia affecting the right side, marked aphasia and probably homonymous hemianopsia on the right. The spinal fluid was normal and the blood pressure 140 systolic and 90 diastolic, and an electroencephalogram showed a focus in the left temporoparietal area. The family and the attending physician rejected the suggestion that arteriography and puncture of the brain be carried out, and the patient was removed from the hospital. On May 22, nine days after the ictus, she was admitted to the Montefiore Hospital[3] in the same condition in which she had been from the onset. Immediately Dr. Davidoff turned down a large bone flap, inserted a needle into the temporal lobe and evacuated 25 cc. of brownish black, old blood from a distance of about 2 cm. below the surface. A small incision into the tip of the temporal lobe opened into a cavity from which similar liquid blood to the amount of about 75 cc., making a total of 100 cc., was removed by suction. Improvement set in immediately, practically on the operating table. The aphasia began to clear, she became alert, her vocabulary enlarged daily, the right hand began to move. The power of the legs returned on the fourth postoperative day, she was able to walk with support on the seventh day and she was discharged on the twelfth day. She still had considerable aphasia, and the hemianopsia persisted. Follow-up report from the family physician tells of practically complete recovery. She is back at her occupation

---

[3] Dr. Leo M. Davidoff gave us permission to use his operative and follow-up notes.

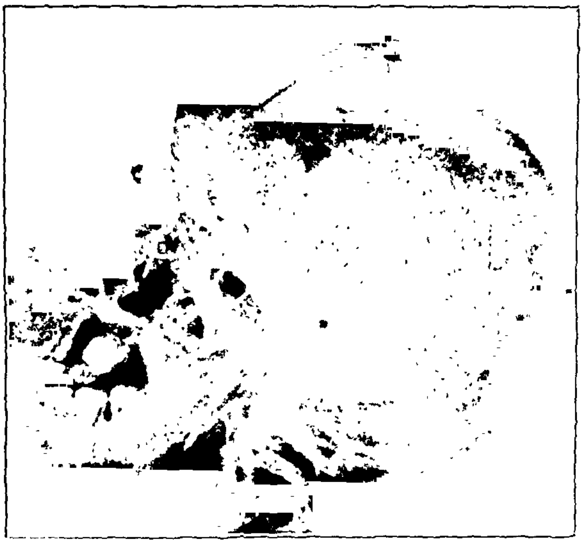

Fig. 3. (case 3).—Elevation of sylvian vessels; hemorrhage.

*Comment.*—Had the arteriogram been done after the first admission to the hospital the diagnosis and localization could have been made at once, and no delay would have ensued, with the risk of irreversible and permanent damage. Fortunately the operative result was good and the recovery excellent. The immediate and almost spectacular result further emphasizes the wisdom of evacuating blood or clot in cases of cerebral hemorrhage.

Case 5.—A white woman, aged 40, suddenly became comatose and when she came to exhibited aphasia and hemiplegia affecting the right side. The blood pressure was 130 systolic and 70 diastolic. The cerebrospinal fluid was clear under a pressure of 204 mm.; there were 7 lymphocytes, and the protein content was 76 mg. per hundred cubic centimeters. The electroencephalogram showed a focus in the left frontotemporal area. A pneumoencephalogram showed slight symmetric ventricular dilatation. Arteriography showed failure of filling of the sylvian group of vessels. The anterior cerebral artery was well filled (fig. 4). This represented a thrombosis. Trephinement was not done.

Case 6.—A white man, aged 26, experienced the sudden onset of aphasia, followed in a few hours by hemiplegia affecting the right side. During the next four months he slowly improved; then his symptoms became more severe. On examination, he had hemiplegia, hemisensory syndrome and homonymous hemianopsia on the right side and considerable aphasia. An electroencephalogram showed a striking depression of the amount and voltage of alpha activity on the left. The cerebrospinal fluid was clear, the pressure 50 mm. Pulsation of the left common carotid artery was markedly diminished. At operation the left internal carotid artery above the bifurcation was hard and without pulsation. Injection of iodopyracet into the common carotid artery visualized the external carotid circulation only. Here, too, we were dealing with a thrombosis. Obviously, trephinement was not indicated.

## SUMMARY

In our series there were 6 cases of intracerebral hemorrhage, 3 cases of cerebral thrombosis and 1 case of thrombosis of the internal carotid artery in the neck. The arteriographic findings in cases of intracerebral hemorrhage depend on the size and position of the hemorrhage and on the amount of edema of the surrounding brain tissue. Our experience is too limited thus far to describe a characteristic type of distortion of the arterial pattern. However, it is likely that the displacement of vessels is simply a mechanical process, depending entirely on the size and position of the hemorrhage. Displacement of blood vessels by tumors can be differentiated with fair assurance. In gliomas there is a fairly characteristic vascular pattern. In the presence of cysts, meningiomas and other slowly growing tumors the vessels of the brain are gradually displaced and more or less shape themselves to the contour of the tumor.

In 3 cases of cerebral thrombosis the sylvian group of vessels failed to fill in the presence of good filling of the anterior cerebral artery. Arteriographic study also led to the discovery of thrombosis of the internal carotid artery in the neck. This diagnosis was suspected in 3 cases. In the one included in this report, it was confirmed by arteriographic study. While arteriography is not new and puncture of the brain for intracerebral bleeding is not novel, the combination of the two specifically for the determination of the nature of the lesion and of its location and as a specific therapeutic measure is. A point of importance worth stressing is that all our patients with remediable hemorrhage of the brain were comparatively young, the oldest having been 50. All were in relatively good health previously. We had a number of patients of advanced age who had severe hypertension, general cardiovascular and renal damage and cerebral arteriosclerosis. Such patients are not good risks. Several died before arteriographic study could be done and others after it had been done with or without attempt at evacuation of the blood or clot. Despite these failures, we feel

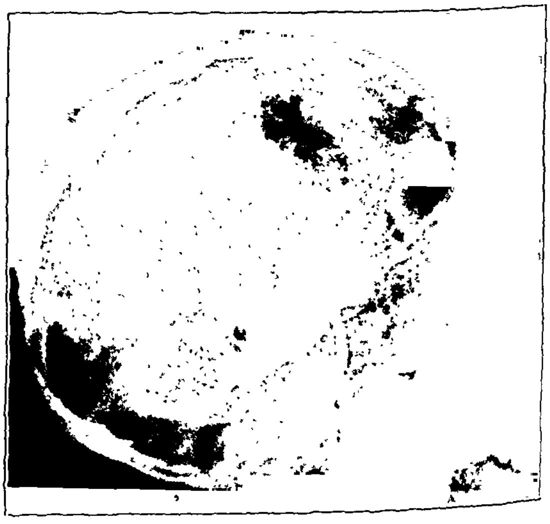

Fig. 4. (case 5).—Failure of sylvian vessels to fill; thrombosis

that the procedure could be carried out if the patient's general condition at all warrants it.

Our conclusion is that arteriography provides a safe method for the differentiation between cerebral hemorrhage and thrombosis and leads to accurate localization. It vouchsafes information not otherwise available. A pneumoencephalogram might also throw light on the diagnosis, but it is a more heroic procedure. Two patients suspected clinically of having subarachnoid hemorrhage due to vascular malformation proved, on arteriographic study, to have hematomas, which were successfully removed. Without making too sweeping claims, we feel that arteriographic study indicates the type of treatment and thus is a therapeutic measure which can in a certain number of cases hasten recovery and prevent permanent damage. Unless, therefore, one is absolutely certain that a thrombosis is present, an arteriogram is indicated.

## ABSTRACT OF DISCUSSION

Dr. Percival Bailey, Chicago: Every physician in active practice is sooner or later faced with the necessity of telling a relative of some patient with cerebral accident that he cannot do anything about it. It is distressing to a physician, whose business it is to do something about sick people. We should be continually seeking for something effective that can be done. There have been certain proposals recently, and my students and the residents in the service of internal medicine invariably ask me three questions. First, is it a thrombosis or is it a hemorrhage? If I say it is a hemorrhage, they want to know why I do not operate and take out the clot. If I say it is a thrombosis, they want to know why we do not inject dicumarol.® Are these proposals likely to be effective? Obviously you cannot prove it by 6 cases. Dr. Wechsler knows that as well as I do. We have experience in these methods of treatment with returns which later prove to be useless. We have to go, in order to prove that this method of evacuating the clot is worth while, into a series of cases in which it has been good in some and not good in others, and then we can perhaps have definite opinions as to whether it is useful or not. The same is true of treatment of thrombosis by injection of dicumarol.® The fact that the nerve cells die quickly would lead one to be hesitant about expecting too much from these methods of treatment. In the case of either hematoma or thrombosis, the destruction of nerve cells is largely due to anoxemia, and you have to cut off the oxygen supply of the blood cell only six minutes in order to have it die permanently. Therefore, it would be logical to institute whatever treatment you are going to institute within six minutes. That, of course, is unlikely to be done, and therefore whatever treatment we institute will not cause a great deal of the nerve cells to recover. Whether we can get enough of them to recover that have not been permanently killed must be proved by statistical record on a long series of cases. The method of differential diagnosis between thrombosis and hemorrhage by arteriography is feasible, I think, especially if one has skill in puncturing the carotid artery through the skin. After one has experience, it can be injected easily through the skin and, therefore, the injection becomes a rather minor procedure. However, it is not entirely without danger. We have had patients whose symptoms have been seriously increased by arteriography apparently uncomplicated.

Dr. Roland P. Mackay, Chicago: Some of Dr. Wechsler's arteriograms seem to be more like phlebograms than arteriograms, because of slight delay before making the picture. I am not sure that it is always so easy to make a diagnosis clinically between a hemorrhage and a thrombosis in the case of ictus, and the fact that Dr. Wechsler has adopted arteriography as an aid indicates that he is often dissatisfied with the clinical diagnosis. At the University of Illinois we have also made arteriographs in such cases. In most of ours the condition has proved to be thrombosis, and we have not, as far as I know, attempted the removal of any subcortical clots in the cases of hemorrhage.

Dr. George Thompson, Los Angeles: It seems to me that Dr. Wechsler has given us an interesting method of treatment for an illness that for the most part seems to us hopeless. I should like to ask him how soon after the onset of a hemorrhage he recommends the aspiration. Does he recommend an open operation on young patients, and how does this technic compare with results obtained by ligation of the common carotid artery?

Dr. I. S. Wechsler, New York: Our work grew out of a sense of impotence when confronted with a cerebral ictus. The method used is simple and has been employed in a large number of cases. The ten slides shown are but a small sample. Only in 1 patient was there aggravation of symptoms after arteriographic study. Fortunately, they receded. Generally the method is safe. It takes a little experience to learn how to distinguish between hemorrhage and thrombosis. Obviously nothing is done in cases of thrombosis. We know that thromboses occur much more commonly than hemorrhages, the ratio being about 3 or 4 to 1, but clinically it is not always easy to state with assurance whether or not there is a hemorrhage, and the arteriogram alone can speak with finality. As to when to do the arteriogram, we felt our way slowly, at first waiting four or five weeks after the ictus and then three and two and one, and now we find that there is no risk in doing it after a few days. Despite the fact that brain cells recover slowly and in some cases not at all, our experience is that recovery can occur even in severe cases in which aphasia and hemiplegia are present and even if the clot or blood is removed a week or two after the ictus. The arteriogram is of value also in cases of thrombosis, as it gives assurance when one wants to administer dicumarol® or heparin, which one would not do in the presence of hemorrhage. We do not ligate the carotid in cases of hemorrhage; we do in cases of aneurysm or other vascular anomaly. We do not ligate the internal carotid because of the risk of hemiplegia, convulsions and death. In ligation of the common carotid, the danger is minimal, as only about 50 per cent of the circulation is cut off. The point Dr. Bailey made about injection through the skin rather than cutting down on the artery is good. One must learn how to get at the artery and avoid the vein, the vagus and the phrenic nerve. Dr. Bailey does it via the skin; so does Dr. Poppen, and so do many others. The only advantage of cutting down on the artery is that, if one wishes to ligate it, it can be done at one sitting. As to venograms, it is a question of timing. Within ten seconds of injection, or at most fifteen, one gets an arteriogram. If the plate is taken after that, the blood is out of the arteries and into the veins, and a venogram is obtained. We take both even though we are not interested in venograms in these cases. With a well coordinated team, one can nearly always get a good arteriogram.

---

**Coronary Disease in Males.**—Dock has recently made observations of great significance. In studying the epicardial coronary arteries of newborn infants, he found that the intima was much thicker in males than in females, and he believes this establishes the basis for the sex difference in the incidence of coronary thrombosis. Careful measurements of the intima and the media of these arteries showed that the average intima in newborn males was 26.5 per cent the thickness of the media, while in females it was only 8.2 per cent. In Dock's words: "The male therefore begins life with about three times as much coronary intima as the female." This very important observation should be confirmed in a much larger series of infants, but there is no reason to question its essential accuracy. Dock is careful to point out that it throws light chiefly on the sex incidence of coronary arterial disease, and states that hypertension and faulty cholesterol metabolism are the most important immediate causes.—H. M. Marvin, M.D., Recent Advances in the Field of Cardiovascular Disease, *Bulletin of the New York Academy of Medicine*, November 1948.

# INTRAVENOUS USE OF FLUIDS IN BRONCHIAL ASTHMA

JOHN M. SHELDON, M.D.
Ann Arbor, Mich.

There probably is an advantage if a subject, especially in the field of therapy, is controversial. But when physicians cannot agree on whether or not to use a medical procedure, it runs the risk of falling into disuse by some and of being regarded in a suspicious light by others. The literature concerning the intravenous use of electrolytes in the treatment of asthma leaves one with a critical view. It is important, therefore, to gather up the procedures which have proved to be useful and to point out those features of intravenous therapy in severe asthma that should be retained as valuable adjuncts of treatment.

One of the first reports on the intravenous use of dextrose in asthma was by Schafir,[1] who in 1927 gave small doses of hypertonic solutions of dextrose intravenously over a period of days to asthmatic patients. Not only was the asthma controlled, but the patients remained free from symptoms for a period of months. Lepak [2] in 1934 reported favorably on the symptomatic control of asthma following the use of concentrated dextrose solution. Kibler [3] and Stoesser and Cook [4] have written enthusiastically of the good results obtained in treating acute severe asthma and have advanced various theories as to why intravenous administration of dextrose was of value. Its beneficial effect on the myocardium and coronary circulation, and possible antidote action on toxic metabolites, were overshadowed by the usually accepted view that treatment with dextrose improved the osmotic pressure of the body tissues, drawing surplus fluid from the edematous allergic tissues and eliminating it by way of the kidneys. There can be no question that there is congestion and edema in the mucous membranes of the reacting allergic bronchi,[5] but the action of dextrose on the edema is not explained to everyone's satisfaction. Experimental work [6] has shown that dextrose given intravenously stimulates the reticuloendothelial system, which is well known for the part it plays in inducing immunity. Thus it may also protect against allergic reactions.

Prince [6a] cited the work of Black,[7] who demonstrated hypoglycemia in patients with allergy; he gave dextrose orally—a few teaspoonfuls daily—and effected remarkable relief from asthma in those treated. Furthermore, if he omitted, or substituted another sugar for, the dextrose, there was a prompt return of the asthma. Prince added the interesting hypothesis that since epinephrine relieves asthma, and one of the actions of that drug is to liberate glycogen from the liver, it is possible that glycogen liberation is as important as the muscle-relaxing property of epinephrine. An impediment was attached to this line of reasoning when Wagner and Rackemann [8] showed that the blood sugar levels and the results of glucose tolerance tests in asthmatic patients are both normal. The confusion was complete when Wilmer and Miller [9] observed that glucose tolerance curves of allergic persons were frequently in keeping with the type seen in higher tolerance than normal. It is entirely possible that these discrepancies may have arisen as a result of differences in the state of nutrition of the different groups of patients or may have depended on a difference in carbohydrate content of the preparatory diet given prior to carrying out the glucose tolerance test.

There is a possibility that the benefit from intravenous use of dextrose, in isotonic sodium chloride solution, may come through the hydration it gives the patient. It is known that there is a loss of body water and sodium chloride during an asthmatic attack.[10] This loss of body fluid takes place in spite of edema of the shock organ which is reacting. In the case of asthma, it is the bronchi which are involved. Stoesser and Cook [11] have shown that adequate hydration and even the presence of stored water in the tissues have no adverse effect on patients with asthma. It is now generally felt that it is poor practice not to keep the patient in status asthmaticus in a well hydrated condition, even if this must be done intravenously.[12]

## USE OF OTHER ELECTROLYTES

Before pointing out the clinical indications and uses for dextrose intravenously in asthma, it might be well to indicate some of the other electrolytes which have been considered in the past. Masserman [13] and Keeney [14] used hypertonic sucrose solution with no ill effects. The latter reported striking relief in six asthmatic persons who were unresponsive to epinephrine. Unfortunately, later work has shown that hypertonic sucrose solution produces renal damage and should never be used.[15]

The work of Stoesser and Cook [16] would indicate that asthma is made worse by administration of sodium chloride, although restriction of sodium to 200 mg. daily has not had a favorable effect in relieving status asthmaticus in my experience.

The use of calcium, either orally or intravenously, is generally regarded as useless in the treatment of severe asthma.[17] Likewise, potassium has not proved

to be of value in relieving an asthmatic paroxysm or in preventing an asthmatic attack.

In summary it would appear that about the only electrolyte which has been able to weather the fire of critical clinical trial is dextrose. This excellent and readily available material should be kept in mind in cases of severe status asthmaticus.[18]

### CLINICAL INDICATIONS AND USES FOR DEXTROSE

Indications for use of dextrose appear to be centered in the severe status asthmaticus patient in whom fluids by mouth are not well tolerated or in those patients in whom orally administered fluids reflexively produce severer asthma. In my opinion it is a means of replacing lost body water and brings about a positive water balance. All patients who have had severe asthma for any period of time are in need of additional caloric intake. Five per cent dextrose administered in distilled water serves as a rapid means of furnishing calories and replacing depleted glycogen stores.

Dextrose in concentration of 10 per cent to 50 per cent has repeatedly been advocated. In my experience, however, 5 per cent dextrose in distilled water is more desirable. Such solutions are isotonic and will supply both the water and calories, a physiologic need in the status asthmaticus patient. The quantity to be given depends on the degree of dehydration of the patient, but, in general, it need not be more than 3,000 cc. in any twenty-four hour period. It is superior to isotonic sodium chloride solution in that there is good evidence that sodium chloride will make the asthma worse.[16]

Contraindications to the intravenous use of dextrose are few. Quattlebaum [19] pointed out that a weakened myocardium is jeopardized by the rapid increase in blood volume which the osmotic action of dextrose produces. "Speed shock" has been known to occur, especially in cases in which hypertonic solutions were used. Anginal pain is said to be produced in some patients with angina pectoris by intravenous use of dextrose. These objections may be minimized if 5 per cent dextrose in distilled water is given, slowly and intravenously (i. e., not more than 500 cc. per hour).

### CONCLUSION

It may be said that the intravenous use of dextrose in the treatment of acute status asthmaticus is of value. It is used primarily to correct alterations of dehydration and to furnish a readily usable source of energy. Intravenous use of saline solutions should be avoided.

## ABSTRACT OF DISCUSSION

DR. J. W. THOMAS, Richmond, Va.: I agree that the intravenous use of electrolytes in the treatment of asthma is still up in the air and requires careful consideration. It is necessary that the various stores of body water remain in a state of equilibrium and that the osmotic pressure exerted by these solutes be within a normal range if a state of health is to be maintained. The four routes of release of fluids from the body include the skin, lungs, gastrointestinal tract and kidneys. The balance of fluids is primarily maintained by the kidneys. It is felt by some workers that there is no close relationship between the transfer of sodium and potassium cation from the intracellular and extracellular phases, and it is further recognized that the oral or parenteral administration of potassium will not necessarily produce an increase in the intracellular concentration. However, if dextrose is given along with the potassium, there will be an increase in some intracellular sodium, and this will be transferred to the extracellular spaces. The maintenance of acid base balance in the body is influenced by the amount of sodium contained in the cells, although it may be in minimal quantities. We are all familiar with the fact that the hydrogen ion concentration of the body fluid is dependent on certain buffers in the blood. The derangement of water and electrolyte metabolism may be produced in many ways and is a component of numerous diseases. Some of those disorders associated with retention of water and electrolyte include: (1) lymphedema, (2) angioneurotic edema, (3) cardiac origin, (4) renal origin and (5) portal obstruction. When one considers that certain severe episodes of asthma might be related to the menstrual cycle, it has to be observed that there is retention of sodium during the intermenstrual and premenstrual periods. It is also observed that the coincident administration of desoxycorticosterone is associated with the retention of sodium. Dehydration, which is frequently observed in asthmatic persons, is an abnormal state of the body water and electrolytes in which the volume of extracellular fluid is diminished and which is accompanied with low concentrations of the extracellular sodium and chloride. When there is a loss of extracellular electrolytes in dehydration, there is also a loss of protein. The skin of many asthmatic persons is dry and inelastic, and some of the mucous membranes appear parched; but these respond with replacement. When one is in doubt, it is always desirable to include blood nonprotein nitrogen as well as urea and other constituents of the blood. In many asthmatic patients whose condition is severe, there is excessive sweating, which may cause some shifting water and electrolyte balance.

DR. EUGENE FOLDES, New York: It seems that a number of diseases are due to general retention of water and minerals. Some diseases are due also to the fact that in response to certain stimuli the water and minerals previously retained throughout the body become mobilized and then accumulate locally in a particular organ or organs. These diseases are usually classified under various headings. For example, epilepsy and migraine, while apparently manifestations of temporary intracranial liquid accumulation, are customarily grouped with the diseases of the nervous system. Eclampsia of pregnancy is attributed to toxemia and eclampsia of infancy to spasmophilia, whereas they also seem to be produced by intracranial liquid retention. If liquid retention develops in the labyrinth of the ear, Ménière's syndrome, usually considered a disease of the ear, is present. If liquid retention occurs in a joint gout, classified as a disturbance of the uric acid metabolism, is indicated. Certain temporary liquid retentions in the skin, in various parts of the respiratory tract and so on come under the heading of allergic diseases; so does, in particular, bronchial asthma, with the attendant edema of the bronchi. In bronchial asthma many factors contribute to the development of the edema of the bronchi. One of these is a local predisposition for the development of edema, the local predisposition being produced by local circulatory changes. Another factor is a disturbance of the general water and electrolyte metabolism, consisting of a sudden mobilization of liquids which then pour from the tissues into the circulation. Some of these circulating liquids are retained in the bronchi, leading to their edema and the clinical manifestations of bronchial asthma. Others will be eliminated through the kidneys, leading to water and salt diuresis and, temporarily, to negative liquid balance. This concept, which I described fifteen years ago, was confirmed by Dr. Sheldon's observations of a negative liquid balance in the asthma attack. But, I would like to point out that injection of 5 per cent dextrose, as suggested by Dr. Sheldon, may lead to liquid retention, and liquids, if retained, may become mobilized and thus may cause the asthma attack. Prevention of mobilization of liquids is necessary, and that consists of prevention of retention of liquids. This in turn can be accomplished by the administration of a diet which is high in proteins and vitamins, but is restricted in carbohydrates, fats, sodium chloride and water. This diet, which I call antiretentional, is effective in many cases of bronchial asthma and is recommended for consideration.

Complete vagotomy was introduced as a main surgical treatment for peptic ulcer by Dragstedt and Owens [1] in 1943. It has been tried since by our group,[2] by Moore and his associates,[3] Machella and his co-workers,[4] Walters,[5] Harkins and Hooker,[6] Paulson and Gladsden,[7] Sanders,[8] Crile,[9] Schoen and Griswold,[10] Schauffer,[11] Beattie [12] and others. Most authors describe favorable results and are continuing use of the operation.

It is becoming increasingly apparent that the usefulness of vagotomy is limited by occurrence of side effects or complications rather than by frequent failure of healing of the ulcers. All authors have confirmed original observations of Dragstedt that usually after vagotomy acidity of gastric secretions is reduced, motility of the stomach is altered and ulcers heal. Duration of these effects must be learned. Study groups [13] that began to use the operation four to six years ago will soon be able to report important late follow-up results.

Justification for use of vagotomy will depend on efficiency of nonoperative or medical treatments, results of other forms of gastric surgical treatment and general effects of interrupting the vagus nerves. Recent reviews of medical and surgical treatments of peptic ulcer have been presented by Bockus,[14] Boles,[15] Ruffin [16] and others. Value and limitations of gastroenterostomy for ulcer have been reported recently by Cooper [17] and of resection by Gardner.[18] General function of the vagus nerves and effects of removal have been presented by Alvarez [19] in a review of the literature of the last sixty years pertaining to experimental and clinical study.

Other reports are directly related to this presentation. Winkelstein [20] and Winkelstein and Berg [21] in 1937 emphasized persistence of acid in gastric secretions of some patients treated by gastroenterostomy or partial resection. They observed an increased incidence of stoma ulcer in these patients and recommended supplementing gastroenterostomy or resection with division of the anterior vagus nerve. This had been done in a group of patients followed as long as nine years. Free acid in gastric secretions frequently persisted. As reported in earlier and subsequent literature, this has been the experience of others who used incomplete vagotomy.

Current efforts are directed toward complete vagotomy. Anatomic studies by Walters and his co-workers,[22] Miller and Davis,[23] Doubilet, Shafiroff and Mulholland [24] and others have indicated that variations of location of the two main vagus trunks and distribution of branches often result in aberrant nerve strands. They expressed the belief that these could be overlooked during transthoracic or subdiaphragmatic dissection.

Interpretation of results of vagotomy must take into consideration completeness of division of the nerves. Therefore, physiologic tests for completeness have been devised. The insulin test popularized by Hollander and his associates [25] has been adopted by most study groups.[26] Stein and Meyer [27] have further studied this test and reviewed related literature. Each group studying vagotomy has described increase of acidity of gastric secretions postoperatively in occasional patients during or after hypoglycemia due to insulin. Dragstedt and his associates [28] expressed the opinion that reduction of volume of gastric juice secreted during the night and decrease over 60 per cent in total hydrochloric acid output from the stomach are equally important evidence for completeness of operation. We observed [2] in patients treated by vagotomy that decrease

of acidity of secretions from the fasting stomach was least among some with greatest obstruction and retention. Since acidity of fasting gastric secretions is not always related to increase of acid following administration of insulin, it is probable that some chemical stimulus or intrinsic gastric secretory mechanism not related to the vagus nerves influences acidity of gastric secretion after vagotomy.

Experiences with vagotomy will be presented in four parts: (A) general results of transthoracic vagotomy for duodenal ulcer, (B) general results of transthoracic or transabdominal vagotomy and drainage for duodenal ulcer, (C) general results of vagotomy for gastric ulcer and (D) general results of vagotomy for stoma ulcer. Experiences are derived from study of 104 patients who had intractable, frequently recurring or complicated peptic ulcer for which they were treated by vagotomy between June 1944 and February 1948. They have been followed through June 1948. The current status of each was ascertained during office visits and by questionnaire. Studies were made in the hospital during the week before operation and during the first two weeks afterward. With some exceptions hospital studies were again repeated three months to one year after vagotomy and thereafter at yearly intervals. Physiologic aspects of these studies presented before this section were reviewed in THE JOURNAL [29] and will be brought up to date in another report.[30]

### A. GENERAL RESULTS OF TRANSTHORACIC VAGOTOMY FOR DUODENAL ULCER (49 PATIENTS)

Thirty-six of the 49 patients had transthoracic vagotomy only as treatment and have not yet required secondary gastric surgical treatment (table 1, A). Symptoms of ulcer had been present three months to thirty-seven years, with an average of ten. The one operation at three months was performed because of pain intractable during medical management in the hospital. Follow-up studies ranged from thirteen to forty-eight months, with an average of twenty-nine. There was no operative death. Hospital stay after vagotomy varied from seven to thirty-nine days, with an average of thirteen. Gastric retention requiring dietary treatment, nightly aspirations of residual gastric content and frequently use of urecholine® (carbaminoyl-beta-methylcholine chloride) necessitated the longer stays. One patient had a cerebral accident and died ten months after vagotomy. Results summarized in table 1 include those for this patient, dealing with his condition before death.

At the time of writing, 30 of the 36 patients had complete relief from discomforts and restrictions formerly associated wtih ulcer. Six occasionally experienced mild epigastric discomfort or ulcer-like distress, which they described as much less troublesome than their former pain. They did not restrict diet. In 1 of these 36 patients a small gastric ulcer developed four months after vagotomy. This did not produce symptoms and healed spontaneously.

At least occasionally, 25 of the 36 patients had minor discomforts, unlike those before vagotomy. These were epigastric fulness, sensations of delayed emptying of the stomach after eating, bowel cramps or looseness of stool. To determine the significance of these symptoms each patient was asked by questionnaire whether he was completely satisfied, moderately satisfied or dissatisfied with the results of vagotomy. The answers are tabulated in table 1 (A 1). Each of the 23 patients completely satisfied and several of the 13 moderately well satisfied patients volunteered enthusiastically favorable remarks about results of operation.

Each patient was also asked his ability to work. Before vagotomy few had been able to work full time. The statements of ability to work are given in table 1 (A 2). Twenty-nine work full time. Three of the 6 able to work only half-time gave periodic diarrhea as the most important cause of disability. One described discomfort immediately after eating, 1 weak spells and 1 bowel cramps as the cause. The patient able to work less than half-time was treated for ulcer and hypertension by vagotomy and splanchnicectomy; this patient later retired from work because of progressive hypertensive vascular disease.

TABLE 1.—*Results of Transthoracic Vagotomy for Duodenal Ulcer (49 Patients)* *

| | No. of Patients |
|---|---|
| A. Transthoracic vagotomy only | 36 |
| 1. Satisfaction of patient | |
| Complete | 23 |
| Moderate | 13 |
| Dissatisfied | 0 |
| 2. Ability to work | |
| Full time | 29 |
| Half time | 6 |
| Less | 1 |
| 3. Reported weight relative to "normal weight" before vagotomy | |
| Greater | 12 |
| Equal | 14 |
| Less | 10 |
| B. Observation and secondary gastric operation required | 13 |
| Retention, gastroenterostomy | 10 |
| Persistence of ulcer, resection | 1 |
| Recurrence of ulcer, pyloroplasty | 1 |
| Intussusception, reduction, pyloroplasty | 1 |

* Frequency of good results, 1 in 2; frequency of secondary gastroenterostomy, 1 in 5, and frequency of postoperative ulcer, 1 in 25.

Each patient was also asked his weight and what he regarded as his normal weight. Most had lost weight before vagotomy because of ulcer. A comparison of normal and reported weights is presented in table 1 (A 3). Twelve patients considered their weight greater than normal and 14 normal. Although 10 patients stated that they now weigh less than normal, stated weights seem compatible with the increased activity and no patient appeared undernourished.

Complaints or symptoms evidently directly related to side effects of vagotomy will be described in more detail in section E of this paper.

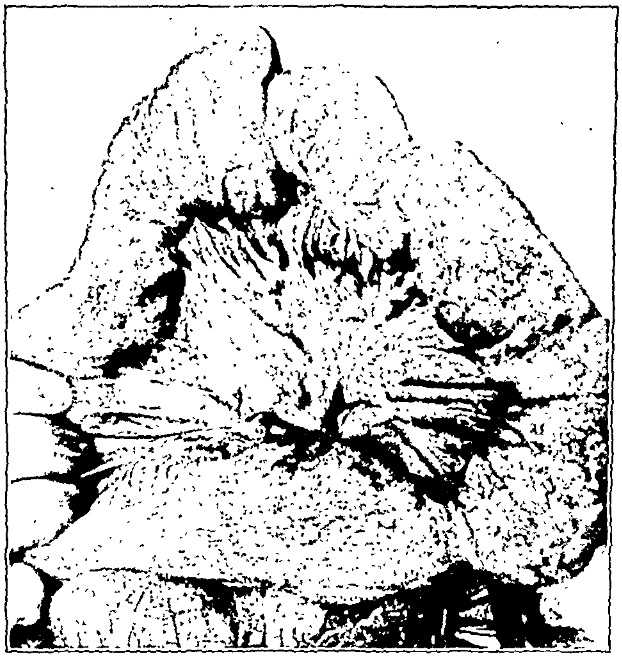
Thirteen patients had transthoracic vagotomy for duodenal ulcer as their primary surgical treatment and subsequently secondary gastric surgical treatment (table 1 B). Histories and examinations before vagotomy were similar to those of the 36 patients treated by vagotomy alone. (Patients apparently seriously obstructed were treated by gastroenterostomy before or at the time of vagotomy and are presented in section B.) Nevertheless, retention necessitated secondary gastroenterostomy in 10. Of the 10, 4 required drainage within the first month after vagotomy (average twenty days). Before vagotomy 1 of these 4 had retention of 5 per cent and another 30 per cent, judged by barium sulfate in the stomach six hours after ingestion. Two did not have retention. Pyloroplasty was used for drainage in 3 and gastroenterostomy in 1.

---

[29] Grimson, K. S.; Baylin, G. J.; Taylor, H. M.; Hesser, F. H., and Rundles, R. W.: Transthoracic Vagotomy, J. A. M. A. **134**: 925-932 (July 12) 1947.

[30] Grimson, K. S.; Rundles, R. W.; Baylin, G. J.; Taylor, H. M., and Linberg, E. J.: Vagotomy: Observations During Four Years, Surgery, To be published.

The remaining 6 patients were treated longer between vagotomy and drainage. Six hour retention of barium sulfate did not occur before vagotomy. After operation 1 patient, with 50 per cent retention twelve days postoperatively and 40 per cent retention forty-five days after operation, had a single hematemesis. After twenty-seven days of medical treatment 100 per cent retention of barium sulfate at six and twenty-four hours developed. Exploration revealed no evidence of ulcer or scar tissue. It was therefore assumed that obstruction and retention were caused by changes of motility following vagotomy. Pyloroplasty relieved retention. The second of these 6 patients had 90 per cent and then 30 per cent six hour retention of barium sulfate during the first year and then noticed tarry stools, which when examined contained occult blood. Exploration did not reveal evidence of ulcer or organic obstruction. Pyloroplasty was performed, and bleeding or obstruction did not recur. Three patients were treated five, six and seven months, respectively. In spite of limitation of diet, frequent residual aspirations and urecholine® given orally or subcutaneously, they continued with 85 per cent or more six hour retention, complained of sensation of fulness, malodorous eructations and weakness and exhibited decided loss of weight. Pyloroplasty in each relieved retention. The sixth patient treated by drainage had an elective pyloroplasty. Ninety-five and 90 per cent retention had persisted during eighteen months, and the patient, although getting along only 15 pounds (about 7 Kg.) below his "normal" weight, complained of a feeling of fulness after eating and weakness. He improved after drainage. This is the only patient in this group in whom exploration revealed evidence of partial obstruction of the duodenum by scar tissue.



Reverse intussusception of the jejunum occurring fifteen months after transthoracic vagotomy without gastroenterostomy. The patient had frequently recurring episodes of severe colicky abdominal pain.

In the remaining 3 patients requiring secondary gastric surgical treatment late after transthoracic vagotomy, exploration was done because of abdominal pain. One complained of abdominal pain since vagotomy and described occasional occurrence of tarry stools. At operation an active duodenal ulcer was seen. Vagus fibers seem completely divided, and a subtotal gastric resection was performed. Fifteen months later pain, tarry stools and hematemesis were again reported. The second patient experienced acute epigastric pain ten months after vagotomy. This persisted one week. Exploration revealed a penetrating ulcer 3 mm. in diameter, which was located in the anterior wall of the duodenum and appeared ready to perforate. A pyloroplasty was performed, and there was no further recurrence of pain. The third patient entered the hospital fifteen months after vagotomy, complaining of frequently recurring episodes of severe abdominal pain. The last episode had persisted eight days. After a week of study, exploration was performed. A reverse intussusception was found 2 feet (61 cm.) below the ligament of Treitz (figure). Although a small amount of free fluid was present in the abdomen, strangulation had not occurred. Another area of intussusception, forward in variety, was seen in the ileum. Both were easily reduced. Because of preceding roentgenologic evidence of retention, pyloroplasty was also performed. There was no evidence of duodenal obstruction by scar tissue. Abdominal pain did not recur.

Clinical results following secondary drainage after transthoracic vagotomy in these 13 patients are not included in the tables and will be described briefly. Follow-up studies since secondary operation range from four to thirty-four months, with an average of eighteen. Hospital stay after drainage varied from ten to twenty-two days, with an average of thirteen. The 4 patients requiring drainage during the first month after vagotomy stated they were completely satisfied. The remaining 9 were treated longer between vagotomy and drainage. One was dissatisfied and unable to work because of recurrence of pain, hematemesis, melena and weakness sixteen months after secondary gastric resection. Another patient was dissatisfied, describing every possible symptom or complication. Neither of these 2 will return for study.

The remaining 7 patients treated longer between vagotomy and drainage were moderately well satisfied. The one in whom perforation of a duodenal ulcer threatened nine months after vagotomy had diabetes with glycosurea and persistent elevation of blood sugar values. He later required restricted diet and insulin. Another, who had reduction of intussusception and pyloroplasty reported seven months later sensations of fulness after meals and weakness. Of the remaining 5 patients 3 described fulness after eating, 1 diarrhea and 1 weakness as the cause of incomplete satisfaction.

Because of gradually developing recognition of the frequent necessity for secondary gastric surgical treatment, poor results when operation was delayed and occasional persistence or recurrence of ulcer, transthoracic vagotomy alone was abandoned as treatment for duodenal ulcer in late summer of 1947. Results of combined operations described in the next sections of this paper are more encouraging.

### B. GENERAL RESULTS OF TRANSTHORACIC OR TRANSABDOMINAL VAGOTOMY COMBINED WITH GASTROENTEROSTOMY AND USED AS A TREATMENT FOR DUODENAL ULCER (29 PATIENTS)

Twenty-nine patients with duodenal ulcer were treated by transthoracic or transabdominal vagotomy combined with pyloroplasty, exclusion[31] or gastrojejunostomy. There was 1 operative death. This was of a patient treated by transthoracic vagotomy and at the same time transabdominal pyloroplasty. He died seventeen days after the two operations of gastric perforation, peritonitis and intestinal hemorrhage. Results in the remaining 28 patients are presented in table 2.

Five of these 28 patients had transthoracic vagotomy and transabdominal gastroenterostomy. Drainage operations were: pyloroplasty in 2, exclusion in 2 and gastrojejunostomy in 1. Two of the drainage operations were performed several weeks before vagotomy and three at the time of transthoracic operation. Symptoms of ulcer had been present eight to twenty-eight years, with an average of seventeen. Follow-up studies ranged from twenty-three to thirty-two months, with an average of twenty-six. Hospital stay after operation varied from nine to thirty-one days, with an average of eighteen. Myocardial infarction developed in 1 patient fourteen months after operation, and death ensued. Results in table 2 include those for this patient and deal with his condition before death.

The remaining 23 patients had subdiaphragmatic vagotomy. Drainage was accomplished by pyloroplasty in 12, exclusion in 9, gastrojejunostomy in 1 and subtotal gastrectomy in 1. Symptoms of ulcer had been present six to twenty-two years, with an average of twelve. Follow-up studies ranged from four to nineteen months, with an average of ten. Hospital stay after operation varied from ten to twenty-two days, with an average of fifteen. There was no operative mortality.

Since there has been no evident difference between results of transthoracic and transabdominal vagotomy, the general clinical results in all 28 patients will be presented together. The single operative death has been described. It occurred among 4 patients treated during one operation by transthoracic vagotomy and transabdominal gastroenterostomy. The immediate postoperative course of the other 3 was febrile, so that use of two incisions has been abandoned. In 1 patient treated by subdiaphragmatic vagotomy, disruption of his abdominal wound occurred on the twelfth postoperative day; five months later adhesive obstruction of the small intestine occurred, which was easily relieved with a Miller-Abbott tube. In another malfunction of the gastroenterostomy stoma developed, requiring enteroenterostomy after seventeen days. Gastroenterostomy stomas frequently functioned poorly during the first several weeks, but with this one exception responded to nonoperative treatment.

The subsequent clinical course of these 28 patients has been encouraging. Each was satisfied with complete relief from discomforts and restrictions formerly associated with ulcer. At least occasionally, however, 12 experienced minor discomforts, such as uncomfortable sensations after eating, bowel cramps or looseness of stools. The significance of these symptoms, determined by statements concerning satisfaction, is presented in table 2. The 21 patients completely satisfied and working full time each volunteered enthusiastic remarks concerning results of vagotomy and drainage. Of the 7 patients moderately well satisfied or able to work only half-time, causes of incomplete satisfaction were given as fulness or discomfort after eating in 3, gas pains in 3 and weakness when hungry in 1.

Examination of comments and details of answers in questionnaires indicates that patients treated by vagotomy and concurrent drainage were the most satisfied of the entire 104 presented in this paper. Nevertheless, comparison of stated weight and "normal weight" (table 2 [3]) indicates that only 16 have gained to or above what they considered their normal weight. The 12 who were less than normal weight were, however, apparently well nourished.

### C. GENERAL RESULTS OF VAGOTOMY AS A TREATMENT FOR GASTRIC ULCER (7 PATIENTS)

Seven patients with gastric ulcer were treated by vagotomy. Symptoms of ulcer had been present three, five, six, nine, ten, eleven and thirteen years. Operations were transthoracic vagotomy alone in 5 and transabdominal vagotomy with concurrent pyloroplasty in 2. Hospital stay after operation ranged from seven to fifteen days, with an average of twelve. Follow-up studies continued ten to thirty-three months, with an average of twenty-three. Results determined by questionnaire are presented in table 3 (A).

Five of these 7 patients described complete satisfaction (table 3 [A 1]). Of these, 4, who had ulcers 1.5 to 3 cm. in diameter located in the antrum, were able to work full time. Ulcers healed in 3 of these 4, as judged by roentgenologic examination. In the fourth, the patient with the largest ulcer, there was recurrence one year after vagotomy alone. The crater then was one-third its original size. It healed spontaneously within six weeks. The fifth patient, who was completely satisfied, had a juxtaesophageal ulcer, 3.5 cm. in diameter, penetrating into the left lobe of the liver. After subdiaphragmatic vagotomy and pyloroplasty bleeding stopped, symptoms subsided, the patient regained normal weight and roentgenologic examination no longer revealed an ulcer. Nevertheless, this patient, at the age of 67, worked only half-time.

---

[31] Exclusion refers to diversion of the pathway for gastric content away from the duodenum by dividing the stomach near the pyloric sphincter, inverting the short distal segment of the antrum, bringing the proximal divided end of the stomach through the transverse mesocolon and connecting it to the proximal jejunum by an end-to-side gastrojejunostomy.

The patient moderately well satisfied had intractable pain from an ulcer 2.5 cm. in diameter, located high on the lesser curvature and penetrating into the liver. Pain was relieved immediately after transthoracic vagotomy, and the ulcer healed within three months, as judged by roentgenologic examination. During the next two and a half years, however, moderate pain similar to that before vagotomy recurred three times, subsiding spontaneously on each occasion without treatment. The present roentgenologic appearance of the stomach is not known, since this patient did not return for further examination.

| Equal | 2 | 4 | 3 |
| Less | 4 | 5 | 5 |

The patient who was dissatisfied had a crater 3.5 cm. in diameter, located along the lesser curvature 3 cm. below the esophagus. Symptoms had been present ten years. Vagotomy was performed without drainage. It relieved pain, but five months later tarry stools reappeared, anemia developed and the size of the ulcer crater had not changed. Because of the possibility of malignancy a subtotal resection was performed. Pathologic examination confirmed the diagnosis of benign gastric ulcer. After resection the weight decreased, bowel habit changed to six or eight soft stools per day and the patient was dissatisfied, being able to work less than half-time.

### D. RESULTS OF VAGOTOMY AS A TREATMENT FOR STOMA ULCER

Nineteen patients had transthoracic or transabdominal vagotomy for stoma ulcer. In 9 stoma ulcer followed subtotal resection of the stomach and in 10 gastroenterostomy (table 3 [B]). The duration of symptoms of ulcer ranged from three to twenty-eight years, with an average of seventeen. Operations were transthoracic vagotomy in 17 and subdiaphragmatic vagotomy in 2. There was no operative mortality. Hospital stay after vagotomy ranged from seven to fifteen days, with an average of ten. Follow-up periods ranged from seven to forty-seven months, with an average of twenty-three.

Five of the 10 patients treated for stoma ulcer occurring after gastroenterostomy reported complete satisfaction (table 3 [B 1]). Of these, 2 have had no difficulty since vagotomy. During the first two years after vagotomy, however, the remaining 3 experienced episodes of acute colicky abdominal pain. Study during three admissions to the hospital of 1 patient and two of another failed to reveal the causes of pain. Attacks subsided spontaneously and did not recur. The third patient experiencing abdominal pain was readmitted repeatedly, and exploration was done twice. During the first operation a strangulated Meckel diverticulum was found and removed. Also, because of preceding roentgenologic evidence of retention distal to a high gastroenterostomy stoma, a pyloroplasty was performed. The second exploratory operation failed to reveal any cause of pain. Episodes of colicky abdominal pain continued, recurring every few weeks until two years after vagotomy, when they ceased spontaneously.

Roentgenologic studies of 2 of these 5 patients revealed that stomas did not function during the first several months after vagotomy opening and that functioning occurred only after one or two years. When one opened, a star-shaped deformity was evident. This later disappeared. Ulcer symptoms did not recur, and each of the 5 patients was well pleased with results.

Four of the 10 patients treated by vagotomy for stoma ulcer developing after gastroenterostomy described moderate satisfaction. Cause of incomplete satisfaction in 1 patient was reported as nervousness, fulness after eating and the occasional occurrence of frequent watery bowel movements. Similarly, another reported nervousness, "gas on the stomach" and inability to sleep. A third described watery bowel movements twice a week. The fourth simply stated that he did not feel quite normal.

The last patient with stoma ulcer after gastroenterostomy was definitely dissatisfied with results. A complicated gastrointestinal disturbance existed before vagotomy. Afterward, although the stoma ulcer healed and the gastroenterostomy functioned well, diarrhea and vomiting became worse. Two years after vagotomy, in spite of treatment with a variety of medicines and parenteral alimentation during repeated admissions to the hospital, he died at home.

Five of the 9 patients treated for stoma ulcer developing after previous subtotal gastric resection described complete satisfaction. One particularly exemplified benefit from vagotomy. During eighteen years she had had repeated massive hemorrhages. These recurred after a gastroenterostomy and subsequently after subtotal gastric resection. Hemorrhages requiring transfusions were occurring every four to six weeks before vagotomy. During the two years that followed operation there was no recurrence of the bleeding. The remaining 4 completely satisfied patients described no ulcer-like symptoms and no inconvenient side effects.

Three of the 9 patients treated by vagotomy for stoma ulcer following resection reported moderate satisfaction. One, two years after vagotomy, stated that diarrhea and nausea became worse during the second year and that strength and weight were less than before resection or vagotomy. Two described troublesome diarrhea without reduction of weight. Both had difficult emotional and environmetntal problems.

The last patient of this group was dissatisfied because of recurring episodes of severe colicky abdominal pain. Twenty-two months after vagotomy and six days after onset of one attack exploratory celiotomy was performed. A forward intussusception of the jejunum and a smaller one in the ileum were found. There was no evidence of strangulation, and reduction was accomplished easily. Examination of the remainder of the small intestine revealed abnormal variations of caliber and shape in several segments of jejunum. After reduction mild episodes of pain again occurred.

## COMMENT

The 104 patients with peptic ulcer described herein each presented symptoms or observations currently acceptable as indications for subtotal or total gastric resection. Patients were not selected except that some were referred because resection had failed. Most were chronic invalids. Treatment was accomplished with but 1 operative death. Although vagotomy or vagotomy and drainage has occasionally produced results which are not entirely satisfactory, we believe that, considering the type of patients treated, rate of rehabilitation has been respectably high. Study has revealed information concerning some of the less satisfactory results.

So far there has been persistence or recurrence of symptoms of ulcer only among patients treated with vagotomy alone. Of 49 originally treated for duodenal ulcer 6 experienced mild ulcer-like symptoms after vagotomy but did not require treatment. One had persistence and another recurrence of duodenal ulcer requiring operation. Among 5 patients with gastric ulcer treated by vagotomy without drainage, 1 had recurrence of mild symptoms, 1 temporary recurrence of a crater and a third persistence of ulcer with symptoms necessitating operation. Ulcer has not as yet occurred after vagotomy and gastroenterostomy, nor have stoma ulcers, consistently healed by vagotomy, recurred.

Intussusception occurred in 2 patients and unexplained severe abdominal colicky pain in 8. These complications occurred in patients treated by vagotomy alone for duodenal ulcer or for stoma ulcer and have not occurred among patients treated by vagotomy and concurrent gastroenterostomy. They may be related to changes of motility of the small intestine produced by vagotomy, and they seem to occur in patients with abnormalities or deficiencies probably associated with retention or with stoma ulcer. Fortunately, each of these patients was asymptomatic at the time of writing.

Serious diarrhea occurred in 3 of 12 patients with vagotomy and resection, in 1 of 10 patients with ulcers of gastroenterostomy stomas treated by vagotomy alone and in 1 patient with retention after vagotomy alone and treated by secondary gastroenterostomy. It did not occur among the 36 patients with vagotomy alone or among the 28 patients treated by vagotomy and concurrent drainage.

Other complications, such as bowel cramps, discomfort after eating and mild periodic diarrhea, have occurred most frequently among patients with vagotomy alone, with vagotomy and late secondary drainage and with vagotomy and resection. They have occurred least often in patients treated by vagotomy and concurrent gastroenterostomy. In general these side effects of vagotomy, when they occur, decreased or disappeared within two years.

Two additional observations deserve comment. One is that complete healing of stoma ulcer, usually prompt, has evidently required a year and a half to two years in 2 patients. The other is that patients in whom gastroenterostomy for retention developing after vagotomy alone was delayed longer than several months were only moderately well satisfied. Symptoms of fulness after eating and weakness persisted.

Although much longer periods of observation are necessary before vagotomy may be finally evaluated, it is our present opinion that explanation and better treatment of side effects will be necessary before vagotomy may be considered a standard treatment of peptic ulcer.

Laboratory studies[30] on the 104 patients reported herein indicate that effects of vagotomy on gastric motility and on acidity of fasting secretions have usually persisted. In half of the patients tested two to four years after operation, however, there were large amounts of free acid in gastric secretions obtained after the occurrence of hypoglycemia due to insulin.

## CONCLUSIONS

1. Although vagotomy without gastroenterostomy yielded good results in half of the patients, occurrence of poor results in the remaining half, including retention requiring secondary gastroenterostomy and occurrence of postoperative ulcer, indicates that this procedure has not been a satisfactory surgical treatment for duodenal ulcer.

2. Vagotomy with concurrent gastroenterostomy has yielded encouraging results as a treatment for duodenal ulcer.

3. Vagotomy has effected healing of stoma ulcer occurring after gastroenterostomy or subtotal gastric resection.

4. Vagotomy has aided in the treatment of benign gastric ulcer, but persistence or recurrence has been frequent. Gastroenterostomy should be done in addition to vagotomy if possible in those few instances in which this operation is elected in preference to gastric resection.

5. In general, side effects of vagotomy seem to diminish or disappear with the passage of time following operation.

# NEWER ASPECTS OF PEPTIC ULCER THERAPY

A. H. AARON, M.D.
WILLIAM F. LIPP, M.D.
and
ELMER MILCH, M.D.
Buffalo

In the past year there have been presented to the medical profession innumerable articles covering every phase of the diagnosis and treatment of peptic ulcer. We believe the proper interpretation of this situation is that so much investigative work and radical changes in the diagnosis and treatment of peptic ulcer are occurring almost daily that it frequently becomes necessary to consider what this progress means to the physician who must apply these advances in the active practice of medicine.

The scope of the problem is demonstrated by the fact that it is admitted that there are in the United States at the present time 4,000,000 persons with peptic ulcer. That these advances in the treatment of ulcer demand consideration is evidenced by the establishment, by the American Gastroenterological Association, of a national committee to study and report on all of these phases in order that, in as short a period as possible, the profession may be acquainted with an accurate and clear interpretation of the ulcer problem.

## ETIOLOGIC ASPECTS OF PEPTIC ULCER

Physiologists, clinicians and surgeons are almost universally agreed that peptic ulcer as it occurs in the stomach and duodenum is directly related to the presence of hydrochloric acid and pepsin in appreciable amounts in the gastric contents. At present the significance of the factor of local tissue or cell resistance is occupying the minds of many investigators, and its importance remains to be established. This accepted physiologic principle will serve as a basis for our discussions. Most of us are willing to accept the concept that the peptic ulcer produced in Mann-Williamson dogs or the histamine-produced ulcer can best be controlled or prevented by anacidity produced by antacid therapy or surgical methods.

## MEDICAL VAGOTOMY

The outstanding results of the recent work on surgical vagotomy as presented by Dragstedt,[1] and now recognized by many workers, are: the relief of pain, transitory reduction of the volume and concentration of acid, alteration in tone and the possible elimination of some factor X originating centrally and mediated over vagal pathways, the last three of which influence ulcer healing.

These concepts have long been appreciated by gastroenterologists and utilized in the medical management of ulcer. Medical vagotomy consists in the blockade of these pathways by adequate doses of the belladonna series. This means the administration of such a product as extract of belladonna to tolerance doses. By tolerance doses we mean the use of the product in much the same way as we were taught to use digitalis. There must be definite evidence of dryness of the mouth and blurring of vision. In our experience no product except one of the belladonna group accomplishes this result.

In addition, medical vagotomy implies an attack on the source or origin of these impulses by carefully educating the patient. It must be explained in understandable terms that fatigue, worry, anxiety, frustration and fear can cause both increased gastric secretion and alteration in motility and tone. Neither drugs nor extensive hospitalization or innumerable and perhaps unnecessary tests will take the place of time expended in education. This is our problem as physicians. As an additional aid we have at our disposal such central acting agents as the barbiturates to help accomplish this purpose.

## ANTACID THERAPY

It is generally conceded that 85 per cent of all peptic ulcers will respond to acid-pepsin control, that is, medical treatment plus central and vagal therapy based on education, sedation and the use of the belladonna series. It is also known that approximately 60 per cent of ulcers will recur in persons so treated. These recurrences may represent failure on the part of the patient to adhere to the regimen or failure on the part of the physician to emphasize the value and the necessity of carrying on the treatment.

In conjunction with medical vagotomy direct control of acid pepsin factors is accomplished by the use of antacids and the bland diet. The multiple antacid preparations available to the profession indicate that we possess no product having all the desired virtues: ease of taking, nonliquid, nonconstipating and a high and prolonged antacid effect. Our choice remains calcium carbonate. Most important is the timing of the administration, and this bears restatement—0.6 Gm. one, two and three hours after each meal and the hour of slumber.

The bland diet is broad, generous, with frequent feedings of food substances, nonirritating, high in acid adsorbability and rich in fats which perhaps diminish acid gastric secretion through the elaboration of enterogastrone.

Medical vagotomy and antacid therapy will result in the control of 85 per cent of the peptic ulcers treated. Few diseases have medical therapeutic measures as effective as this combined treatment.

## PROPHYLAXIS OF PEPTIC ULCER

Of the 85 per cent of the peptic ulcers that respond to medical treatment recurrences can be expected in about 60 per cent. It is the control of these that represents one of the foremost advances in the treatment of peptic ulcer in recent years.

If the prophylactic principles of the prevention of peptic ulcer had been as completely utilized as those for the prevention of such an infectious disease as typhoid, in our opinion, there would be fewer recurrences. Unfortunately, we have no preventive inoculations, but do have specific advice and medical therapy, the value of which has been emphasized by Alvarez,[2] Winkelstein[3] and others.

---

From the University of Buffalo School of Medicine and the Buffalo General Hospital.

Read in a joint meeting of the Section on Surgery and the Section on Gastro-Enterology and Proctology at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 25, 1948.

[3] Winkelstein, A.: The Prophylaxis of Peptic Ulcer, Gastroenterology **5**:457 (Dec.) 1945.

In the person with a known peptic ulcer the following measures can definitely aid in the prevention of recurrences:

1. The person who anticipates exposure to emotional strain should be prepared for such an event by as thorough a grounding as possible in the importance of factors such as fear, anger and worry, by the active practitioner and not by the psychiatrist. There are not enough psychiatrists available at the present time to take care of the serious problems that belong to them, and the practitioner must assume his place in this disease.

2. Sedation. The use of adequate doses of the belladonna group and the barbiturate sedatives will definitely decrease or eliminate central vagal ulcerogenic stimuli. On the slightest indication of return of symptoms, the patient of his own accord should resume his restricted diet and medication.

3. We have found it helpful to exclude alcohol and to limit the use of coffee and tobacco.

4. The ulcer patient should "beware the Ides of March" and the autumnal equinox. Why, we do not know, but it is at these times that with the slightest indication of symptoms he should resume his planned therapy.

### ENTEROGASTRONE

Ivy and his co-workers[4] reported that the administration of an extract of duodenal mucosa rich in enterogastrone was remarkably effective in preventing the formation of postoperative jejunal ulcer in dogs prepared by the method of Mann-Williamson. Ivy[4] and Sandweiss[5] have designated enterogastrone as the hormone derived from either the duodenal or intestinal mucosa which suppresses gastric secretion and acidity and gastric motility, and which may also contain a factor which increases the resistance of the mucosa to ulceration. A further observation was that after the enterogastrone therapy was discontinued the ulcers failed to develop in the animals during a period of 8 to 14 months, and they surmised that in some manner the animals were immunized. Since this observation a preparation of enterogastrone has been made available to the profession and used in the treatment of peptic ulcer. There have been varying reports of success and failure following its administration.

In the past year we were generously supplied with an adequate amount of enterogastrone so that we were able to administer daily hypodermic injections of enterogastrone to a small group of 10 patients. These were all men, with an average age of 53 years. Six had chronic duodenal ulcers, 1 a gastric ulcer and 3 jejunal ulcers. The average duration of symptoms was 11 years; the longest period was 26 years and the shortest 3 years.

The patients received no other therapy of any type except for the bland diet. The duration of treatment with daily injections of enterogastrone was as follows: 6, 5, 7, 8, 8, 2, 11, 10, 7 and 8 months, respectively. The only untoward reaction noted was the development of subcutaneous nodules. All were followed clinically and roentgenologically. The patient treated for 2 months was one who showed improvement but discontinued treatment. Of the 6 patients with duodenal ulcer, 4 showed a poor clinical response, with the persistence of definite roentgenologic evidence of the presence of ulcer. Two showed definite freedom of symptoms, with healing demonstrated by roentgenogram.

The patient with a gastric ulcer, who refused operation, showed no clinical or roentgenologic improvement with enterogastrone therapy. Of the 3 patients who had jejunal ulcers 2 had excellent clinical results, with evidence of healing by roentgenogram. One showed a doubtful response, and at the end of 7 months antacid therapy was instituted, with subsequent improvement.

We think that this is a group of patients different from some of the others studied in that, despite their continued ulcer symptoms, they were willing to continue with the enterogastrone therapy and bland diet as the only form of treatment.

In a recent communication, Sandweiss[5] stated that his clinical results with enterogastrone in comparison with the diet-alkali regimen indicated that enterogastrone failed to produce more satisfactory results than the diet-educational-medicinal plan. In personal communications Palmer and Pollard both stated that in their opinion their results with enterogastrone were not better than those obtained with conventional medical treatment. From our results we were inclined to agree with this conclusion.

Ivy and Grossman[6] concluded that enterogastrone extracts prevent postoperative jejunal ulceration in a high percentage of Mann-Williamson dogs, and from their studies of human beings believe that the results are not unrelated and further exploration of the value of enterogastrone is warranted.

### RESECTION OF GASTRIC AND DUODENAL ULCERS IN GENERAL HOSPITALS

It is our feeling that surgical treatment for peptic ulcer is based on the same physiologic principles that apply in medical therapy, namely, the reduction of the acid pepsin factor to as near a point of permanent gastric anacidity as possible.

Surgical treatment for the intractable ulcer not amenable to adequate medical therapy is, in our opinion, best accomplished by high gastric resection including the first portion of the duodenum and 80 per cent of the stomach with a Polya type of restoration of continuity of the gastrointestinal tract. This procedure removes not only the acid-secreting portion of the stomach but also the hormonal area and permits neutralization of the gastric acidity by the alkaline jejunal contents. Mechanically it also prevents the pooling of food and gastric juices, which we feel is of great importance.

During the years 1940 to 1946,[7] 153 high gastric resections for peptic ulcer performed by nine different surgeons at the Buffalo General Hospital were available for follow-up studies. These patients were recalled and rechecked during the year 1947. Eighty per cent of these patients had no free acid; 13 per cent had free acid values below 13 units, and 7 per cent had high acid values. Of these patients 76 per cent considered themselves well, while 14 per cent of them considered themselves very much improved. The remaining 10 per cent were not improved and had marginal ulcers.

When one considers that these 153 patients were gastric cripples who had failed to respond to excellent medical treatment, 90 per cent is a high salvage mark for any other type of surgical procedure to better. In other words, of every 100 patients in whom adequate medical therapy has failed, high gastric resection has restored 90 per cent to a sound and useful economic existence.

[7] Howland, J. M.: Proc. Staff Meet., Buffalo General Hospital.

In this group the only unfavorable postoperative sequela has been a failure to gain weight. We have not been impressed with the so-termed dumping syndrome as reported by other observers. A review of the mortality rates following this radical procedure at the Buffalo General Hospital corresponds to the experience of surgeons elsewhere. It must be remembered that we are reporting the results from a large general hospital where a number of surgeons were operating. During the years 1940-1944, the mortality rate was 14 per cent; in 1945 it was 9 per cent and in 1946 down to 5 per cent.

In the last 40 consecutive cases at the Buffalo General Hospital, with nine different surgeons operating for intractable peptic ulcers, there was 1 death. At the other teaching hospital associated with the University of Buffalo, The Meyer Memorial Hospital, in the last 80 consecutive cases there was no death. In other words, in 120 consecutive cases in which operation was done in two large general hospitals there has been 1 death, representing a mortality rate of less than 1 per cent.

### GASTRIC ULCER

It is our feeling that the patient with gastric ulcer who does not exhibit freedom of symptoms and roentgenologic evidence of complete healing within four weeks should be operated on. We do not temporize with gastric ulcer. We know that there is a 15 per cent error, in our hands and in the hands of others, in gross pathologic diagnosis as to benignancy or malignancy. If there is to be any reduction in the appalling high mortality rate of gastric carcinoma, the gastric ulcer must be operated on early.

In a recent communication, Welch and Allen[8] and Marshall and Welch[9] advised a more immediate attack on gastric ulcer, omitting any effort to prove that it would heal under medical care, restricting this medical procedure to young patients in whom the ulcer is small and on the lesser curvature or on the posterior wall. Welch and Allen[8] called attention to the fact that the incidence of delay in seeking treatment for carcinoma of the stomach has not changed since 1927. In other words, the patient has not sought care and the profession has not utilized well proved criteria for indication of early resection.

### MASSIVE HEMORRHAGE

For years the attitude toward the treatment of massive hemorrhage has fluctuated between the extremes of medical and surgical management. This cyclic behavior indicates continuing dissatisfaction with prevailing mortality figures. Each form of treatment has its enthusiastic proponents. The principal cause of this recurring difference of opinion is the acknowledged difficulty in establishing criteria that will enable one to select those patients who would not respond to medical management. The interpretation of the term massive hemorrhage varies from group to group. To us it means massive continuing bleeding with an exhibition of the classic picture of collapse: pallor, air hunger, hypotension and tachycardia with decreased blood volume. In the majority of instances this precarious state will respond to medical treatment consisting of massive and continuous multiple *transfusions, oxygen and opiates.* There will be some who will not survive, and some whom surgical treatment will save. Yet it seems to us that at the present time the surgical mortality rate is too high, even in competent hands, to justify the general use of gastric resection as the treatment of choice in massive hemorrhage.

Others (more recently Stewart[10]) have stated that operative intervention requires a team of from six to eight highly trained personnel, meticulous preoperative preparation, including laboratory studies, a skilled surgeon, resident and nursing staff and adequate blood, since in the majority of instances this intensely coordinated activity will take place during the night when bleeding so frequently occurs. Moreover, it is not generally appreciated that successful surgical intervention requires considerable surgical treatment, such as the removal of the ulcer (the point of bleeding) as part of the gastric resection, and this can often be technically *difficult and sometimes impossible.* In these instances, in addition to the resection one must be sure that the pancreaticoduodenal artery is ligated. It is obvious that such a service is not generally available. Consequently, it is our feeling that in the present state of our knowledge and skill we must advocate the conservative medical treatment of massive hemorrhage.

It is to be hoped that future studies will demonstrate a reduction in surgical mortality rates, so that operation may be more widely used as a relatively safe method to attack the bleeding at its source. None will deny that local control with mechanical measures is the most efficient means of arresting hemorrhage in whatever portion of the body it may occur. It becomes apparent, therefore, that sound criteria must be developed to allow selection of those patients to be operated on.

We reemphasize that we are discussing patients suffering from massive continuing bleeding with the classic picture of collapse. These patients should immediately have *multiple transfusions* in addition to the conventional conservative therapy, as much as 2,000 cc. of blood in an hour if necessary. At the end of 3 hours of this treatment, if there is no appreciable clinical improvement in the patient, as indicated by a rise in blood pressure, reduction in pulse rate and disappearance of air hunger, we suggest that the patient is a candidate for immediate operation, as it appears that he is losing blood as rapidly as it is replaced. If this persists for a few more hours this shock state will become irreversible, so that even operation will not save the patient. However, if at the end of 3 hours clinical improvement is manifested, we continue the same treatment, and at the end of 6 hours we discontinue all therapy and carefully observe the patient. If he once again starts to bleed massively, the same treatment is given and the patient operated on at once. If, however, the patient does not show evidence of massive bleeding after discontinuance of all therapy, the medical plan of therapy is continued. Under this regimen as much as 5 liters (5,000 cc.) of blood may be administered in the six hour period.

If the concept of surgical treatment is strengthened by future studies, then, taking a lesson from World War II, it might be desirable to give transfusions while transporting patients with hemorrhage from smaller communities to centers with the facilities described herein.

[10] Stewart, J. R.: Personal communication to the author; Scientific *Exhibition of the American Medical Association, Section of Surgery,* June 1948.

However, until this hope is translated into fact we must continue to urge conservative medical management as a general procedure in the management of massive continuing hemorrhage. At the present time we feel that the first step is to have in each large hospital teams to carry out the medical treatment we have presented; we look forward to the further contributions from Stewart and his co-workers and others to establish more firmly the idea of immediate surgical intervention. In 32 of their patients operated on, the mortality rate was 16 per cent. In 21 patients not operated on, the mortality rate was 29 per cent.

### SURGICAL VAGOTOMY

With the advent of increased supradiaphragmatic and subdiagphragmatic surgical vagotomy, the gastroenterologist, as well as the surgeon, realized the necessity of arriving at a conclusion as quickly as possible as to the merits and disadvantages of this operative procedure. The American Gastroenterological Association, with this idea in mind, appointed a committee on ulcer with Dr. David Sandweiss as general chairman and Dr. Sara M. Jordan as chairman of the subcommittee on vagotomy to accumulate the data as to the status and progress of surgical vagotomy up to the present time.

At its recent meeting in Atlantic City, a panel, consisting of Dr. Harry L. Bockus, moderator, and Drs. Francis D. Moore, Allen Wilkinson, Lester R. Dragstedt, Julian M. Ruffin, Franklin Hollander, Jay Earl Thomas, Thomas E. Machella and E. N. Collins, discussed the problem by direct presentation and question period, fixing their attention on the surgical procedure of vagotomy.

From these sources we quote by consultation of their stenographic notes:

> The opinion that transthoracic or transabdominal vagotomy as usually performed is seldom complete is concurred in by all modern physiologists and is based on sound anatomic considerations: (1) Small esophageal plexuses may escape the operator's notice, and (2) the gastrointestinal vagal nerve ends in a ganglionic plexus within the walls of the stomach.
>
> Vagus fibers may enter the musculature of the esophagus and emerge again at lower levels. In animals, at least, severance of all vagal fibers gives rather uniform results—unfavorable, even death.
>
> Complete vagotomy in experimental animals regularly causes digestive disturbances severe enough to cause death. These comprise hypomotility of the stomach and hyposecretion of the stomach and pancreas and possibly the intestines, together with a vigorous hyperirritability of the intestines.
>
> These changes are interpreted as being due mainly to loss of the tonic activity of the abdominal vagus. Evidence is reviewed which indicates that transthoracic or transabdominal vagotomy in experimental animals, and presumably in human beings, is seldom complete, and it is suggested that the relative harmlessness of this operation as usually performed is due to this fact.
>
> Attempts to accomplish more nearly complete vagotomy in human subjects would probably be unwise.
>
> Tonic activity of the vagus may be essential for the production of gastrin.

The general conclusions from the stenographic notes are:

1. In 2,500 cases reported the mortality rate was 1.7 per cent.
2. Eighty-five to 90 per cent have relief of pain.
3. The recurrent hemorrhage rate was 1 per cent.
4. There is an over-all recurrence of some form of symptoms in 15 to 20 per cent.
5. Atony has been a temporary factor.
6. Ninety-three per cent who had had a resection were wholly satisfied.[11]

Dr. Moore called attention to the dangers of the use of statistics. He called to mind the fact that it was the desire to secure the facts of such committee investigations but to avoid standardization and too all-inclusive conclusions.

Dr. Ruffin stated that the failures or recurrences reached as high as 20 per cent and emphasized the necessity of carefully choosing the patient on whom a vagotomy is to be performed. The patient who had a marginal ulcer following resection was a most likely candidate for vagotomy, and in repeated massive hemorrhage he believed that the same would hold true and that the debilitated patient will withstand vagotomy rather than resection.

Dragstedt stated that the pain relief by vagotomy is due to the profound reduction of the free hydrochloric acid concentration of the gastric contents and, in addition, relaxation of the tonus and motility of the stomach. He was sure that it is not due to sensory block. Dr. Dragstedt was convinced that it is possible to do a physiologically complete vagotomy in a human being when the nerves are divided along the lower part of the esophagus; he called attention to the fact that the surgeon who does the prevailing type of subtotal gastric resection also sections the vagus nerves. It was agreed that the severed nerves do not regenerate and do not reunite.

At the present time it is our feeling that gastric resection is the surgical procedure of choice in the majority of patients who prove resistant to conventional medical therapy, on the basis, as we stated earlier, that high gastric resection produces greater opportunity for an antacid stomach, in our hands, over a longer period of time.

Vagotomy has certain merits and definite disadvantages. For several years to come it must be considered as an experiment in human gastric function. Certainly, vagotomy reduces acid secretion, at least temporarily. In addition it may remove a mysterious factor X, central in origin, mediated over the vagal pathway and perhaps related to the tissue resistance of the mucous membrane of the upper part of the gastrointestinal tract. Most spectacularly, it relieves ulcer pain almost immediately. Probably a complete vagotomy is impossible anatomically, because of fibers which course within the esophageal walls. This may not be a disadvantage, because in the experimental animal complete section of the vagus nerve leads to disastrous consequences, if not death. In the majority of instances there is satisfactory control of ulcer symptoms for a temporary period of time.

Despite these advantages there are important disadvantages. Most significant is its temporary effect. It is known that over a period of months or several years there is a restoration of acid to normal amounts, and this implies a return of the ulcer environment. Secondly, there has already been demonstrated a rather high percentage of recurrences, even with bleeding. Finally, undesirable side effects may occur, such as gastric retention and diarrhea, which may be temporary or susceptible of medical control but some of which will necessitate additional surgical treatment.

If the procedure is to be done, it seems more reasonable to employ it in conjunction with some sort of drainage operation, such as gastroenterostomy. However, the value of this combined procedure over gastric resection remains to be proved. This is not to say that there is not a place for vagotomy in the management of intractable ulcer. It has special value in the treatment of marginal ulcers, where it seems to be the first procedure that should be tried because of the technical difficulties so often inherent in direct surgical attack against these lesions.

## ABSTRACT OF DISCUSSION

ON PAPERS BY DRS. AARON, LIPP AND MILCH, AND DRS. GRIMSON, RUNDLES, BAYLIN, TAYLOR AND LINBERG

Dr. Lester R. Dragstedt, Chicago: The early surgeons who worked in this field seldom, if ever, secured a complete division of the vagus fibers to the stomach. I am certain, however, that the method is receiving an adequate test at the present time. Some 9,000 vagotomies have been done in the United States, and possibly 2,000 have been done in various European countries. At the University of Chicago Clinics, our experience with vagotomy for peptic ulcer falls into three periods. During the first period, which extended from January 1943 to the middle of 1945, I performed a transthoracic vagotomy on 80 patients with various types of peptic ulcer. The method was then abandoned because of the intercostal pain so frequently associated with the thoracotomy, and also because of inability to explore the stomach and other abdominal viscera. From June 1945 to about July 1946, we performed a routine gastric vagotomy and gastroenterostomy on all patients with duodenal ulcer. The results following this method of treatment were highly satisfactory. However, when I reflected on the fact that in the first series, there was a large number of patients on whom vagotomy alone had given an excellent result, it occurred to me that an unnecessary gastroenterostomy was being done in many cases. Since July 1946 gastric vagotomy alone has been performed on about 80 per cent of patients with duodenal ulcer. In the remaining 20 per cent, an additional gastroenterostomy has been carried out because of actual or threatened pyloric stenosis. Up to December 1947 a total of 370 patients with various types of peptic ulcer had been treated by vagotomy at the University of Chicago Clinics. In 202 of these, vagotomy alone was performed. In this latter series, there was 1 death. One hundred and sixty-eight patients had vagotomy plus gastroenterostomy or some other type of gastric surgical treatment. In this group, there were 3 deaths. In the total series, there were 326 duodenal ulcers, 30 jejunal ulcers and 14 gastric ulcers. In the entire series, vagotomy was proved to be complete by physiologic tests in 340 of the patients. In only 2 of these was there a recurrence or persistence of ulcer. In 1 patient with a duodenal ulcer which remained healed for four and one-half years, a benign gastric ulcer developed in an almost anacid stomach. The gastric content after a test meal was neutral, but free acid was secreted in response to the stimulus of histamine. The second patient with recurrence following complete vagotomy had an associated pyloric stenosis. Because of this, vagotomy and gastroenterostomy were carried out. Because of subsequent obstruction at the gastroenterostomy site, a second operation was performed with an entero-enteroanastomosis between the jejunal loops. This procedure was ill advised, because it diverted the alkaline bile and pancreatic juice away from the anastomosis, and an ulcer subsequently developed at the stoma.

Dr. Francis D. Moore, Boston: My co-workers and I have used vagotomy chiefly without other procedure. In the recent past we have performed more of the drainage operations. It may well be, as Dr. Grimson has pointed out, that the patients who have vagotomy with partial gastroenterostomy will feel better and get along more satisfactorily. We should not assign that entirely to the drainage function of the gastroenterostomy but should remember that the operation or gastroenterostomy alone is effective in dealing with a reasonably high percentage of patients with duodenal ulcer. The long term result in this group will be determined by the number in whom jejunal ulcers later develop at the new anastomosis. In our series of 116 patients subjected to vagotomy, we have had 11 per cent recurrence, the term to include the appearance of either symptoms revealed by milk and alkali or symptoms plus demonstrable ulcers. These late recurrences have come after long postoperative periods—one, two or three years—with negative reactions to insulin tests in the interval, and they cannot be ascribed to incomplete vagotomy. They are a manifestation of the fact that the autonomic nervous system was not contrived by nature to be operated on and removed. It serves primitive functions, and some years after removal physiologic resumption of function occurs. Whether this is due to "overlap" or anatomic regeneration, I do not know. We have had several patients whose symptoms were minor, transient or negligible, but who have either enough symptoms to suggest trouble, a roentgen change pointing the way to recurrence or a resumption of insulin reactivity. It is my feeling that in spite of the fact that 11,000 vagotomies have been allegedly done the world over, it is still too soon to feel confident with this procedure. I am going to follow our series of about 100 patients very closely, seeing them frequently, taking roentgenograms frequently and making physiologic studies frequently before I apply this procedure widely—or wisely—to many patients.

Dr. A. C. Ivy, Chicago: We are fortunate to have men performing this operation who have a basic training in physiology and are applying physiologic methods in an attempt to evaluate carefully the results of the operation. This should render it possible to evaluate this operation much sooner than, for example, gastroenterostomy or resection of the pyloric portion of the stomach was evaluated. The vagus exercises several influences on the alimentary tract: a motor, a secretory and probably a vasomotor influence. It also mediates afferent sensations from the alimentary tract. The predominant action of the vagus on the cardiac sphincter is to promote relaxation in advance of a wave of primary peristalsis. When the vagus is sectioned, achalasia of the cardiac sphincter tends to occur. It persists in the dog from two weeks to a year. The same observations have been reported in human beings. The vagus manifests a tonic effect on the postural tone of the stomach. Section of the gastric vagi causes a loss of postural tone, or resistance to stretch; that is, the stomach is more readily distended with air than it was before operation (*Arch. Int. Med.* **25**: 6 [Jan.] 1920). This disturbance of postural tone in the dog lasts from two weeks to six weeks. The vagus has an effect on the peristaltic tone of the stomach. In 1920 I reported that section of the vagi above the diaphragm in the dog results in the abolition of type 2 and 3 hunger contractions in the stomach; these are contractions on tone. In other words, according to my observations vagi section abolishes the tonic type of motility for a period of at least two years. Of course, peristaltic activity occurs, but it occurs only on low tone. In my opinion, that is the reason why ulcer pain occurs so infrequently after section of the vagi. The predominant effect of the vagi on the pyloric sphincter is inhibitory, according to my observations. The effect on the sphincter of Oddi, according to my observations, is primarily motor. I am not certain what the effect of the vagus is on the small intestine. It has been difficult for me to demonstrate in the dog any effect of the vagus on the small intestine. The vagus is predominantly inhibitory for the ileocecal sphincter. I have not seen any result from stimulation of the vagus below the heart on the colon of the pig, monkey or dog. I do not have a good explanation to offer for the diarrhea observed in some patients after vagotomy. Regarding the secretory action of the vagi, everyone is agreed that complete supradiaphragmatic section of the vagi abolishes the cephalic phase of gastric secretion. In addition, my observations in human beings indicate that section of the vagi decreases the responsiveness of the human stomach to histamine. I have not been able to demonstrate that the vagus has any effect on the secretion of mucus. The other point is that reflex cardiac and respiratory arrest may occur during the performance of a transthoracic vagotomy. I have performed approximately 250 such operations and have observed cardiac arrest in approximately 1 out of 25 dogs. The heart can be resuscitated uniformly by cardiac massage and the intracardiac injection of 1 mg. of epinephrine hydrochloride and 0.6 mg. of atropine sulfate.

**Dr. Waltman Walters**, Rochester, Minn.: Vagotomy has been performed at the Mayo Clinic 177 times, 77 times by me and 100 times by other surgeons. The operation is clearly indicated in cases of recurring ulceration after partial gastrectomy. Excellent results have been obtained in a two year period when vagotomy was performed for gastrojejunal ulcer which had followed gastroenterostomy. These results compare favorably with the results of partial gastrectomy in similar cases of gastrojejunal ulceration, when the patients are studied after a lapse of from five to ten years or more. The results in the treatment of duodenal ulcer when vagotomy is combined with gastroenterostomy seem little better than when gastroenterostomy is performed alone. The same may apply to cases in which pyloroplasty with removal of the duodenal ulcer is accompanied with vagotomy. It has seemed to us best to interpret the results of vagotomy in the treatment of duodenal ulcer, therefore, in that group in which the vagotomy was performed without other operations on the stomach, which would tend to promote gastric emptying, decrease the amount of gastric secretion and reduce the acidity of the stomach by the reflux of alkaline, duodenal and biliary secretions through the gastroenteric stoma or by removal of part of the secreting portion of the stomach, as in partial gastrectomy. Excellent results in the treatment of duodenal ulcer were obtained in only 65 per cent of cases from vagotomy alone and unsatisfactory results in 35 per cent; from vagotomy combined with gastroenterostomy excellent results were obtained in 88 per cent and unsatisfactory in 12 per cent. From vagotomy combined with excision of the ulcer and pyloroplasty, excellent results were obtained in 80 per cent and unsatisfactory in 20 per cent. In the treatment of gastrojejunal ulcer which followed gastroenterostomy, the results from vagotomy alone were excellent in 83 per cent and unsatisfactory in 17 per cent. When the ulcer followed gastric resection, the results of vagotomy alone were excellent in 88 per cent and unsatisfactory in 12 per cent. Vagotomy alone thus gave excellent results in 86 per cent of cases of gastrojejunal ulcers in which it was employed. Excision of the ulcer and reconstruction of the gastrojejunal anastomosis combined with vagotomy were carried out in 6 cases and gave excellent results in 3. The poorest results in the whole series were obtained in this small group of cases.

**Dr. Walter L. Palmer**, Chicago: I shall limit my remarks to duodenal ulcer. It is important to remember that duodenal ulcer is a benign disease, that the great majority of patients get along very well with the standard methods of medical management such as Dr. Aaron outlined. As Dr. Jordan has pointed out, the indication for operation is intractability; we all have different ideas as to what constitutes intractability. In my judgment, the incidence of intractability does not exceed 10 per cent. What is the cause of intractability? It seems to me to be due to high grade gastric secretion. Dr. Levin has shown in his study of fasting gastric secretion that the average normal person in twelve hours will secrete 661 mg. of hydrochloric acid, whereas the average patient with duodenal ulcer secretes 2,242 mg. of acid, or three and a half times as much. In 5 so-called intractable patients whose secretion was studied by Dr. Levin the nightly twelve hour output of acid was 3,900 mg., 3,800, 2,900, 3,900 and 5,500 mg., respectively. If there were some means of regularly producing complete and permanent gastric anacidity, the ulcer problem would be solved. I do not know of such a method. There is no procedure, either medical or surgical, short of total gastrectomy, which regularly or invariably produces permanent anacidity and permanent cure. Dr. Dragstedt has shown that one of the best methods of lowering gastric secretion is vagotomy. He and Dr. Moore have pointed out, however, that there are occasional patients in whom vagotomy does not reduce the acid, presumably because the procedure is incomplete. Subtotal gastrectomy brings about anacidity, as Dr. Aaron pointed out, in perhaps 80 per cent of cases, but not more than that. In the surgical treatment in the intractable cases, one must choose between subtotal or total gastrectomy and vagotomy with or without gastroenterostomy. For the reasons Dr. Aaron indicated, I have never approved of subtotal gastrectomy for duodenal ulcer.

**Dr. Sara M. Jordan**, Boston: There are two comments I should like to make. One is a request, and the other is a protest. First the protest, and that is against vagotomy for gastric ulcer. My co-workers and I have been interested for about twenty-five years, have been able to follow a great number of gastric ulcers and have recently studied them. We are impressed, first of all, with the necessity for absolute and complete healing of the gastric ulcer. Secondly, we are impressed with the necessity for the maintenance of healing. In other words, we regard the unhealed ulcer and the recurrent ulcer as dangerous, as potentially malignant. About 20 per cent of all gastric cancer arises in what looks like a benign gastric ulcer. Ten per cent of ulcers in our series actually proved to be malignant. Therefore, if we trust vagotomy to heal the ulcer, without making a most accurate careful check-up, I think that we then run a great risk of that small percentage of ulcers becoming malignant without our knowledge. I believe that resection is the operation for gastric ulcer if it needs any operation. Secondly, the request—and this is a very earnest request—that all surgeons do as Dr. Francis Moore said he was doing, follow up vagotomy cases. The National Committee for the Study of Peptic Ulcer of the American Gastro-Enterological Association will call on you during the next year for those results. We hope by careful appraisal of them to come to an opinion within a year which will promote or cause us to discontinue this operation of vagotomy.

**Dr. R. L. Sanders**, Memphis, Tenn.: My co-workers and I have done vagal resection in 122 cases of duodenal ulcer and gastrojejunal ulcer. For gastric ulcer, we have continued performing a resection, usually supplementing it with vagotomy. All of these operations have been performed through an abdominal incision. Being abdominal surgeons, we naturally prefer this approach; moreover, we feel that it is definitely advantageous in that the pathologic process may thus be visualized. In addition, the patient's convalescence is more comfortable and complications are fewer than those following the use of the transthoracic approach. In more than 85 per cent of the 122 cases, we have combined a gastroenterostomy with vagal resection. The majority of the remaining vagotomies were performed early in our experience with the procedure. We soon found that without a gastroenterostomy patients had considerable difficulty with fulness and distress following operation, whereas with the addition of a gastroenterostomy they had little trouble in this respect, and then usually for only a short while, until the tonus of the stomach was restored. Two patients had a gastroenterostomy subsequent to vagal resection, because of persistent discomfort. Several had a mild or moderate diarrhea postoperatively, though, with one or two exceptions, this sooner or later subsided. We have been well pleased with the results of bilateral vagal resection. Approximately 85 per cent of our 122 patients have obtained excellent results, with complete relief of their ulcer symptoms. Approximately 10 per cent have had a fair result, continuing to experience mild or moderate epigastric discomfort or recurrent episodes of diarrhea. All of this group feel that the operation has been well worth while. The unfavorable outcome in the remainder may be attributed either to the fact that the resection was inadequate or the patient had a definite neurosis. We have observed that the best results followed combined vagal resection and gastroenterostomy in young persons with an active ulcer and, preferably, though not necessarily, high gastric acid levels. We have had no operative deaths, nor have any of our patients exhibited evidence of recurrent ulcer.

**Dr. Otto Porges**, Chicago: As Dr. Palmer pointed out, the problem of the treatment of ulcers is in lowering of the secretion of the stomach. We know that certain drugs lower secretion: 1. Atropine and its derivatives are effective, but they do not work satisfactorily in nontoxic doses. 2. There are the antihistaminic drugs. They, too, work but in large doses which produce major side effects. 3. Sodium nitrate depresses stomach secretion in large doses only, causing untoward reactions. I conceived the idea of using all these drugs combined, and I examined the reaction in animals. I found that these three drugs, combined in low doses, lower the gastric acidity satisfactorily. I gave two or all three of these drugs combined to patients with ulcer, and I saw that the pains were gone from the outset of this therapy and there were no untoward side effects. Plenty of work has still to be done in this direction. I cannot report yet about the future of these cases, but work is in progress in this direction. I mention my research only because I think that it might be of use to one or the other of you.

Dr. R. S. Dinsmore, Cleveland: I was extremely impressed with Dr. Aaron's discussion about the important group of patients who have massive recurrent hemorrhages and who in some instances have to be operated on as emergencies. Interestingly enough, he has stated that in this group 1 out of 4 or 1 out of 6 of these patients treated medically or surgically are lost. Many of these patients bleed from deep posterior wall lesions, and efforts at controlling the bleeding locally have resulted in failure, so that gastric resections must be resorted to. It is an advantage immediately to divide the stomach, thus allowing an adequate and quick exposure of the posterior area. In some of these patients, especially those who continue to bleed during the operation, arterial transfusions may be of advantage. There is one complication of vagotomy that is seldom mentioned, which is a technical one—that of injury to the splenic pedicle. My own efforts in attempting a plastic procedure on them have been eminently unsuccessful; in nearly every instance an immediate splenectomy is indicated.

Dr. Erwin Levin, Chicago: During the past several years, Dr. Palmer, Dr. Kirsner and I have studied the nocturnal gastric secretion in normal persons and in patients with duodenal ulcer and with gastric ulcer. The average output of hydrochloric acid during the night for normal persons averaged 661 mg. It was below 500 mg. in 50 per cent. In patients with duodenal ulcer the average output of acid was 2,242 mg. It was below 500 in 1 per cent of the studies. The amount was greater than 1,000 mg. in 80 per cent and greater than 2,000 mg. in more than 50 per cent. In patients with gastric ulcer the average output of acid during the night was 454 mg., approximately two thirds that of normal persons. The amount was less than 500 in two thirds of the studies. These data were submitted to statistical analysis, and the conclusions are as follows: The output of acid is significantly greater in persons with duodenal ulcer than in normal persons and in patients with gastric ulcer is significantly less than in normal persons. What bearing does this have on vagotomy for peptic ulcer? When Dr. Dragstedt adopted this procedure, it was based on the physiologic principle that patients with ulcer have a hypersecretion of acid, presumably due to increased vagal activity. The data just presented for patients with duodenal ulcer and also the decrease of acid to normal or subnormal levels after vagotomy support this contention. Therefore, I agree that in patients with duodenal ulcer in whom operation is indicated the procedure of choice is bilateral vagotomy, with or without gastroenterostomy as may be indicated. However, in patients with gastric ulcer a different situation exists. The aforementioned data indicate that increased vagal activity is not present in this group. The output of acid in the majority of patients is less than that found in healthy normal persons. Furthermore, to my knowledge no evidence has been presented to date that the gastric secretion is decreased significantly in patients with gastric ulcer who are low secretors when bilateral vagotomy is performed. The question, therefore, arises: "Is vagotomy indicated in patients with benign gastric ulcer?"

Dr. A. H. Aaron: Since in 40 per cent of experimental dogs ulceration along the lesser curvature has followed vagotomy, I do not know why one should not expect to find it in human beings. I rather think that it is for those who propose vagotomy to do as Dr. Moore suggested: sincerely consider and evaluate the results in the approximately 11,000 vagectomized patients. This will be accomplished, as Dr. Jordan reported, when we have the results from the national committee which has been appointed by the American Gastroenterological Association to bring together much of this information. One should think seriously before one chooses to do too many of them. Others have called attention to the infrequency of hemorrhage following vagotomy. Nevertheless, Dr. Ruffin found about 1 per cent recurrence of hemorrhage in the group from Dr. Grimson's clinic. A mortality rate of 1 per cent shows results in this group to be similar to results in the group with gastric resection. One must bear in mind, as Dr. Palmer said, that only about 15 per cent of the patients are considered for surgical procedures. We must emphasize that we are not going to treat gastric ulcer by vagotomy. We must assume the responsibility that such a lesion may be malignant unless it is definitely demonstrated that it has healed clinically, roentgenologically and gastroscopically and shows absolutely no tendency to recur. The medical treatment is based on the sound principles which produce excellent results and if adequately followed up will prevent recurrence. I do not want to dodge the surgical issue. For those patients that I see who require surgical intervention, I use gastric resection, because there has been the lowest mortality rate with this technic and the environment for ulcer formation is reduced to a greater extent than with any other surgical method.

Dr. Keith S. Grimson, Durham, N. C.: Dr. Dragstedt's recommendation that the abdominal rather than the transthoracic approach be used generally for vagotomy is warranted by our results. Gastric retention necessitating secondary gastroenterostomy and caused by scar tissue also occasionally occurred among our patients treated by vagotomy alone, but with one exception the obstruction was a result of failure of relaxation of the pyloric sphincter and was not caused by scar tissue. We cannot agree entirely that the insulin test always determines completeness of vagotomy. This and also volume and acidity of gastric night secretions may vary after vagotomy, depending on stimuli other than those of nervous origin. Gastric motility pattern as recorded, with a 300 cc. intragastric balloon, seemed to us the least variable and probably most reliable test for completeness of interruption of the vagus nerves. Dr. Moore's careful study of vagotomy without gastroenterostomy has led to a conclusion in agreement with ours that vagotomy alone should not be used as a general treatment for duodenal ulcer. It is of interest that his observation of return of highly acid gastric secretions during insulin hypoglycemia in a few patients two or more years after operation agrees with observations reported by us; however, in our series a majority of the patients followed two to four years have had little or no acid even during five hour insulin tests. Dr. Ivy's experiences with vagotomy have been in accord with our observations on human beings and on animals. Achalasia has been described after this operation in animals. We have previously reported that temporary obstruction of the lower part of the esophagus occasionally followed vagotomy in human beings. This never persisted, did not roentgenologically resemble achalasia and was apparently related to spasm or edema following trauma of operation rather than to failure of peristalsis. We agree with Dr. Ivy that secretion of acid after administration of histamine, caffeine or insulin is frequently reduced after vagotomy in patients. We must emphasize, however, that patients and dogs differ with regard to effects on gastric motility and that, although gastric ulcers often develop in dogs, a gastric ulcer developed in only 1 patient in our series, and this healed within two months. We agree with Dr. Walters that a five or ten year period of observation will be necessary before proper evaluation of vagotomy as a treatment for peptic ulcer is possible. We agree that gastroenterostomy alone is only rarely indicated as the sole treatment for peptic ulcer. This reservation evidently does not apply to combined use of subdiaphragmatic vagotomy and gastroenterostomy, which apparently has been a satisfactory treatment as employed in our patients and during the present follow-up period.

In the antiquity of many races there is evidence that liver was used to relieve illness. The modern epoch of its therapeutic use was opened when Minot and Murphy discovered that the eating of liver could be effective in producing remissions in persons with pernicious anemia in relapse.[1] Many of the patients soon complained about the amount of liver it was necessary to ingest, however, and the efforts of many investigators were directed toward producing potent liver extracts. These extracts have been studied and used extensively in clinical medicine; yet the pathogenesis of macrocytic anemia has remained far from clear.

Two advances were reported recently from our clinic. The first of these was the observation that pteroylglutamic acid (folic acid) produced a hemopoietic response in persons with certain types of macrocytic anemia in relapse.[2] The second observation was that 5-methyl uracil (thymine), an entirely different chemical compound, was capable of producing a similar response in persons with these diseases.[3] Despite the fact that these compounds had a profound effect in promoting blood regeneration, neither of them proved to be a complete treatment for pernicious anemia. Neither of them protected the nervous system in all patients against degeneration nor, when the degeneration had occurred, could it be remitted by either or both of these compounds.[4] Certain persons also experienced severe glossitis against which these compounds were not effective. Both of these compounds have been effective in treating tropical sprue and nutritional macrocytic anemia.[5] The amount of thymine which must be given to be effective is several thousand times the amount of folic acid required; thus, thymine is not a practical therapeutic substance.

The finding of the effect of specific therapeutic agents of known chemical composition on the cells of the bone marrow has opened a fresh and fertile field for the clinical investigator. While we have been studying the effects of thymine and folic acid and trying to redefine the macrocytic anemias in the light of all the various loose threads which enter the meshwork of their pathogenesis, we have steadily observed that a large amount of these substances was necessary to produce a satisfactory hemopoietic response. When we considered that relatively little highly potent liver extract is needed, we were led naturally to think that other substances are contained in liver extract.

The most recently discovered antianemic substance is vitamin $B_{12}$, a chemical compound of unknown chemical structure. Using the microbiologic method of Shorb,[6] Rickes, Brink, Koniuszy, Wood and Folkers isolated vitamin $B_{12}$ from liver.[7] It was found to be effective in 3 cases of pernicious anemia by West,[8] in 2 cases of pernicious anemia, 2 cases of nutritional macrocytic anemia and 1 case of nontropical sprue by Spies, Stone and Aramburu,[9] and in 2 cases of tropical sprue by Spies, Garcia Lopez, Milanes, Lopez Toca and Culver.[10] The present communication is concerned with the accumulation of data directed toward answering two questions: (1) What is the effect of vitamin $B_{12}$ on blood regeneration in persons with nutritional macrocytic anemia, tropical sprue and pernicious anemia? (2) What is the effect of vitamin $B_{12}$ on subacute combined degeneration in persons with pernicious anemia? These studies were done in the Nutrition Clinic of the Hillman Hospital, Birmingham, Ala., the General Calixto Garcia Hospital, Habana, Cuba, and the School of Tropical Medicine, San Juan, Puerto Rico.

## MATERIAL AND METHODS

Of utmost importance in the selection of patients for testing vitamin $B_{12}$ was an accurate diagnosis. Before admitting the patients to the hospital to serve as test subjects for the purpose of studying the effectiveness of vitamin $B_{12}$ as an antianemic substance, we determined that each one fulfilled the following four criteria:

1. Macrocytic hyperchromic anemia
2. Red blood cell count of 2,500,000 or less
3. Color index of 1.0 or more
4. Megaloblastic arrest of the sternal bone marrow

Additional criteria used in classifying the cases as to the type of macrocytic anemia were: for pernicious anemia, the absence of free hydrochloric acid in the gastric contents after histamine stimulation; for nutritional macrocytic anemia, the presence of free hydrochloric acid in the gastric contents and diarrhea characterized by dark brown stools; for tropical sprue, the presence of free hydrochloric acid in the gastric contents, a flat glucose tolerance curve, diarrhea with

fatty stools and loss of body weight. According to these criteria a group of 21 patients was selected. This group included 4 patients with nutritional macrocytic anemia, 1 patient with nontropical sprue, 11 patients with tropical sprue and 5 patients with pernicious anemia.

Fourteen additional patients known to have pernicious anemia who also had subacute combined degeneration were selected for the purpose of studying the effect of vitamin $B_{12}$ on these neurologic changes, by use of the following criteria:

1. They either had or had had macrocytic anemia.
2. They had had megaloblastic arrest of the bone marrow.
3. They had histamine refractory achlorhydria on two or more occasions.
4. They had a sudden and recent onset of symptoms arising from the posterior and lateral column of the spinal cord.
5. They had had no antianemic therapy since the symptoms developed.

The patients were admitted to the hospital, and all but 5 patients with tropical sprue in Puerto Rico were given a diet devoid of meat and meat products, and they were maintained on this diet throughout the course of the study. The following laboratory studies were made by methods previously described[11]: examination of the peripheral blood,[12] which included frequent red and white blood cell determinations and packed cell volumes and daily reticulocyte counts; sternal bone marrow studies; oral glucose tolerance test; gastric analyses; gastrointestinal series and study of the small intestine, and examination of the stools for ova, parasites and occult blood.

OBSERVATIONS

The characteristic hematologic response to the injection of vitamin $B_{12}$ is shown in the table. The increase in the reticulocytes, number of red blood cells and amount of hemoglobin in a case of nutritional macrocytic anemia (case 2) is shown in figure 1; in tropical sprue (case 8), in figure 2, and in pernicious anemia (case 18), in figure 3.

In each case the administration of vitamin $B_{12}$ was followed by a striking clinical improvement. Between the third and fifth day after the injection of vitamin $B_{12}$, the patients volunteered that they felt stronger and that their appetites had returned. When soreness and burning of the tongue was present, it disappeared by the fourth or fifth day after therapy and the redness subsided. In the cases of sprue, the abdominal distention subsided, the volume of the stools decreased and the patients became less gaseous on the sixth or seventh day following therapy.

* This patient ate liver fifteen days after the injection of vitamin $B_{12}$.
† Seven days after the injection of 4 micrograms of vitamin $B_{12}$, this patient was given 100 mg. "diopterin" (pteroyl diglutamic acid) by mouth.

In the 14 cases of addisonian pernicious anemia, 9 with severe and 5 with mild subacute combined degeneration, the parenteral administration of vitamin $B_{12}$ was followed by remarkable improvement. Prior to its injection each of the patients complained of pain, tingling and stiffness in the extremities, and the patients with severer disease complained also of numbness, tingling and stiffness of the joints. These symptoms diminished progressively during the first ten days after the injection. Within two weeks after the administration of vitamin $B_{12}$, a dramatic improvement in the observations of peripheral nerve–posterior column involvement was observed in each case. This is illustrated in the following representative case history.

### REPORT OF A CASE

S. H., a 71 year old white woman, became ill in 1939. Her illness was characterized by an insidious onset of dyspnea, palpitation and weakness. Three years later she was admitted to the Nutrition Clinic of the Hillman Hospital where a diagnosis of addisonian pernicious anemia with mild subacute combined degeneration of the spinal cord was made. This diagnosis was based on the following observations: red blood cells 2,130,000, hemoglobin 8.2 Gm. (53 per cent), color index 1.2, megaloblastic arrest of the bone marrow, histamine refractory achlorhydria and the presence of subacute combined degeneration of the spinal cord. She improved following the injection of potent liver extract. She returned to her home but would not continue maintenance therapy.

In March 1948, when she returned to the clinic, she complained of soreness of the tongue, which she said felt "scalded," anorexia, general weakness, dyspnea on exertion, constipation, numbness of the feet, legs and hands and slight swelling of the feet and legs. She attributed these symptoms, which had been slowly progressing for several weeks, to increased work and anxiety caused by the illness of her husband. Significant physical observations were: moderate pallor of the skin, nail beds and conjunctivas; hyperemia of the distal portions of the tongue and hypotrophic vascular papillae in the same areas; severe impairment of the tendon reflexes in the lower extremities (knee jerks absent, ankle jerks hypoactive); no vibratory perception at the ankles and knees, and only slight at the pelvis; suggestive slight impairment of position-motion sensibility of the toes; hypoesthesia to light touch in the lower two thirds of the thighs and in the legs, feet and fingers; hyperesthesia to pain in the lower part of the thighs and in the legs and slight pitting edema of the lower legs. Observations of the blood were: red blood cells 2,010,000, white blood cells, 5,250, hemoglobin 7.5 Gm. (48 per cent), packed cell volume 23 per cent, mean cell volume 114, mean cell hemoglobin 37 and mean cell hemoglobin concentration 33.

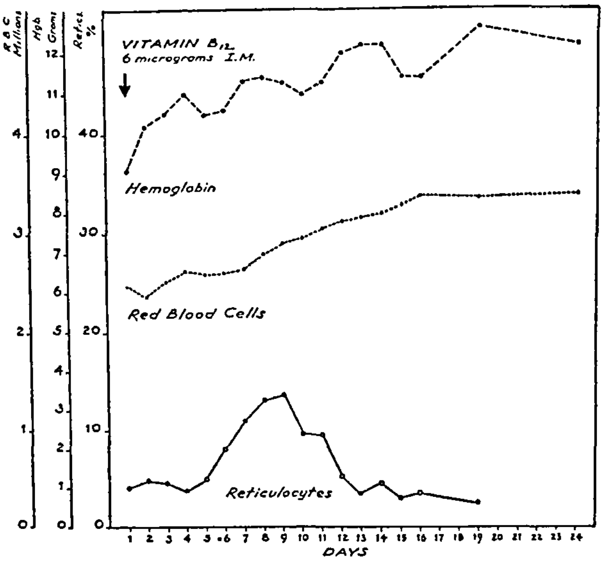

Fig. 1.—Hemopoietic response of a patient (J. M.) with nutritional macrocytic anemia to vitamin $B_{12}$.

Beginning on March 2, 1948, she was given 10 mg. of folic acid by mouth daily for eighty days. A peak reticulocyte count of 28.7 per cent occurred on the ninth day of therapy. By the eightieth day of therapy her blood values were: red blood cells 4,220,000, white blood cells 4,800, hemoglobin 14.6 Gm. (94 per cent), packed cell volume 44 per cent, mean cell volume 104, mean cell hemoglobin 34 and mean cell hemoglobin concentration 33. She improved very much generally; the glossitis subsided, her appetite improved and her strength increased to such an extent that she resumed doing her housework. The paresthesias persisted, but there was no evidence of further progression of the neurologic symptoms.

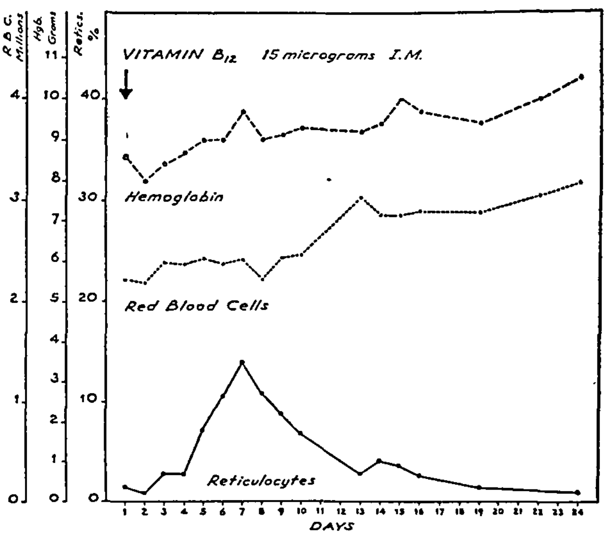

Fig. 2.—Hemopoietic response of a patient (F. M.) with tropical sprue to vitamin $B_{12}$.

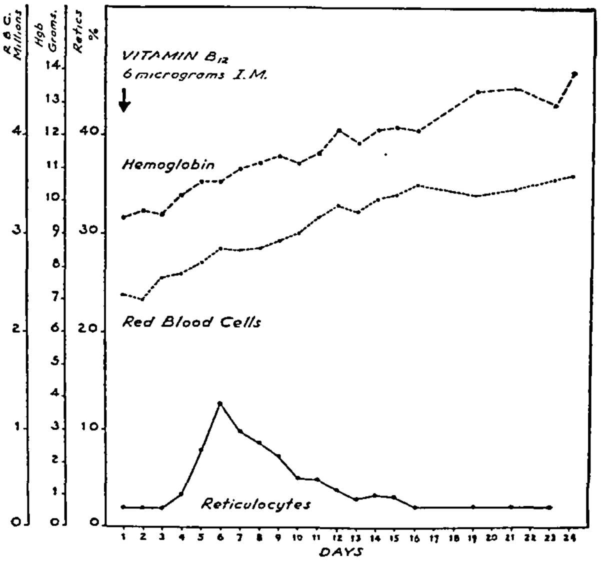

Fig. 3.—Hemopoietic response of a patient (T. C.) with pernicious anemia to vitamin $B_{12}$.

The folic acid therapy was terminated during the last week of May. Several weeks later a gradual decrease in the red blood cells and hemoglobin was noted and numbness recurred. By August 18, her red blood cell count was 2,740,000 and her hemoglobin 8.1 Gm. (53 per cent). She complained of general weakness, anorexia, dyspnea on exertion and paresthesias of about the same severity as noted before. The physical observations on this occasion were essentially the same as at the time of the last examination. There was no evidence of further progression of nervous system disease. Treatment with 10 mg. of folic acid daily by mouth was resumed. Within a period of six days, a neurologic relapse developed. Overnight, locomotion became so severely disturbed that she was unable to walk without assistance; her knee and ankle joints would give way or turn, and the lower extremities were weak. Her feet and legs felt cold and stiff. Her hands felt stiff and weak, and the difficulty she had in using a knife and fork, buttoning her clothes and combing her hair was very disturbing to her. The paresthesias of the lower extremities and hands became severe, and those of the hands began to spread proximally to the wrists; anorexia and tightness, fulness and distention of the abdomen and severe constipation were the outstanding symptoms.

The most significant physical changes observed at this time were obvious disturbance of locomotion and impairment of function of the hands. She was unable to arise from a sitting position and walk without assistance, and severe difficulty in picking up and manipulating small objects was demonstrated.

Twenty-five micrograms of vitamin $B_{12}$ was injected parenterally, and she received the same amount intramuscularly at the end of each forty-eight hours until a total of five doses was given. On the fourth day of treatment she was able to walk without support. On the fifth day she was able to perceive touch and pain in her extremities, whereas, prior to this time, it had been absent in the feet, legs and distal part of the fingers. By this time, she could discriminate texture with her fingers. On the sixth day after therapy was started, she had little weakness and little unsteadiness in walking. She was walking well on the tenth day, and the Romberg sign was no longer positive. The ankle jerks and knee jerks, which had been absent, returned. Twenty-six days after the initiation of vitamin $B_{12}$ therapy, she appeared to be over the acute exacerbation of her neurologic disease, and by this time her red blood cell count, which had been 2,050,000, had risen to 3,040,000 and her hemoglobin had increased from 9.3 Gm. (60 per cent) to 10.5 Gm. (68 per cent).

### COMMENT

This case is typical of many we have seen when folic acid neither protects against nor relieves subacute combined degeneration of the spinal cord once it has developed. This patient did not respond as well to therapeutic agents in general as many patients in the clinic, but when she cooperated long enough to be treated to completion, her blood values approached the accepted normal. The most interesting observation is that in the early stages of acute relapse of subacute combined degeneration, the lesion is evidently a "biochemical" one, for there is such prompt relief from the symptoms arising from the posterior and lateral column.

There is much difference among physicians regarding the pathogenesis of pernicious anemia, sprue and nutritional macrocytic anemia, yet it is obvious that an accurate diagnosis is the essence of clinical investigation. Hence, the cases chosen were such that any experienced physician would concur in their diagnosis. Despite the fact that these anemias occur throughout the world, certain types are much commoner in some countries than in others. In temperate zones only sporadic cases of sprue are seen, whereas in some tropical lands sprue is endemic. Pernicious anemia is much commoner in the temperate zones than in the tropics. Nutritional macrocytic anemia occurs rarely in the North Temperate Zone but occurs frequently in the South Temperate Zone and in the tropics. Recently we saw a patient in Cuba with achylia gastrica, steatorrhea and combined systemic disease. Recently in Puerto Rico we saw 3 cases of sprue with combined systemic disease. One of the patients had achylia gastrica, and the other 2 had free hydrochloric acid in the gastric juice. Gastric juice from the Cuban patient, when incubated with ground lean beef and fed to a patient known to have pernicious anemia in relapse, induced no hemopoietic response. Similar studies are being made on the gastric juice from the 3 patients in Puerto Rico. The symptoms arising from the combined systemic disease in the Cuban patient who had both pernicious anemia and sprue disappeared after the administration of vitamin $B_{12}$. The symptoms arising from the involvement of the spinal cord in 2 of the Puerto Rican patients slowly decreased after the administration of vitamin $B_{12}$. The third Puerto Rican patient was relieved of his combined systemic disease by liver extract therapy. As would be expected, the blood values of the 3 patients from Puerto Rico and the patient from Cuba all increased. The Cuban patient with achylia gastrica had very little gastric juice but after many days we obtained enough through a tube to send to Birmingham for incubation with beef. The incubated mixture was then given to a patient with pernicious anemia according to the original method of Castle. The pernicious anemia patient who responds well did not respond to this mixture, suggesting that there was a deficiency of an important element in the gastric juice of the Cuban patient.

The Cuban patient was then given by mouth 50 micrograms of vitamin $B_{12}$ concentrate (Merck) and observed for ten days. There was no clinical or hematologic or neurologic effect. Twenty-five micrograms of $B_{12}$ concentrate was then incubated with 75 cc. of normal fasting human gastric juice obtained from a person with duodenal ulcer. This mixture was given to the anemia patient and he had a hematological and clinical response. The reticulocytes began to rise on the third day and rose in a characteristic fashion. The symptoms of combined system disease greatly lessened and the patient got up and out of bed for the first time in a considerable period. This observation shows clearly that normal human gastric juice when incubated with $B_{12}$ is able to affect the utilization of $B_{12}$.

### SUMMARY AND CONCLUSIONS

Vitamin $B_{12}$, per unit of weight, is the most effective antianemic substance known. It has been found to produce a hematologic response in persons who have pernicious anemia, nutritional macrocytic anemia and tropical sprue. It is the only pure chemical substance known to be effective in relieving subacute combined degeneration in persons with pernicious anemia.

When vitamin $B_{12}$ is administered to suitable patients, under controlled conditions, reticulocytosis occurs and is followed by an increase in red blood cells, platelets and hemoglobin. A striking clinical response parallels the hemopoietic response. About the time the reticulocytes begin to rise, the patients volunteer that they feel stronger. Those whose appetites have failed have a sudden desire for food. Symptoms arising from subacute degeneration of the spinal cord in persons with pernicious anemia are benefited by the administration of vitamin $B_{12}$. The severe glossitis present in some cases of macrocytic anemia heals spectacularly. In patients with sprue and nutritional macrocytic anemia there is a decrease in the number of stools and a tendency for the stools to return to normal.

The dosage of vitamin $B_{12}$ varies greatly from patient to patient. We have observed a slight effect following the injection of as little as 4 micrograms and complete failure on as much as 10 micrograms. A response has occurred in every case when several times these amounts were administered. Perhaps the average patient will respond maximally to 100 micrograms or less. Most patients seem to respond minimally to from 8 to 10 micrograms.

Vitamin $B_{12}$ has no effect on the leukopenia of infections or the idiosyncrasies due to drugs, idiopathic purpura, secondary anemias, aplastic anemia or leukemia.

In the management of any of these syndromes of macrocytic anemia which respond to specific therapy, we follow these five principles:

1. Make a positive diagnosis early in the course of the disease.
2. Institute persistent and intensive therapy promptly.
3. Prescribe an amount of the therapeutic agent in excess of that just necessary to maintain the patient's blood at a normal level.
4. Prescribe a diet rich in animal proteins.
5. Treat promptly all coexisting diseases and any complicating factors.

We wish to stress that there is no place for careless diagnosis and casual treatment when liver, liver extract, "ventriculin" (preparation of desiccated hog stomach), folic acid and vitamin $B_{12}$ are employed as therapeutic agents. The failure of physicians to detect sprue, macrocytic anemia, pernicious anemia and other related anemias usually leads to a chain of unfortunate circumstances for the patient.

# THE FUTURE OF MEDICINE IN TIMES OF WAR

JULES VONCKEN, M.D.
Liége, Belgium

The International Committee of Military Medicine, pursuing further its campaign to obtain improvement in the conditions of aid to the wounded and sick during wartime, has studied, through its Medico-Legal Commission, the position of medicine in the international order.

During armed conflicts physicians find themselves with a mission to fulfil which is unique in its extent and complex in its moral grandeur. In all epochs of civilization it has been an axiom of the most elementary international law that "hostes dum vulnerati fratres" (enemies when wounded become brothers). Since the nineteenth century, which saw the first international codification of duties involved in the organization of aid to the wounded, in the form of the Red Cross Convention, this concept has continued to advance, and it is consoling to observe that in spite of all the setbacks of political rapprochment, whether in the League of Nations or in the United Nations Organizations, the only structure which has been maintained is the Red Cross, probably because it places emphasis on respect for the suffering. Suffering being the same throughout the world and thus becoming a superior imperative before which nations must bow as before all physical scourges or epidemics, it is in common misfortune that even enemies dream of uniting in order to combat the scourge effectively.

It is the same with the scourge of war: In order to improve with a little hope the suffering of the wounded and sick, nations are willing to accept, for the common interest, respect for the humanitarian conventions.

Is not this an element of rapprochment which should at all costs be utilized and developed under present conditions? To those of good will, the coming diplomatic meeting, which will be held in Geneva in the spring of 1949, will give a great opportunity. This conference, which will bring together the plenipotentiaries of all nations of the world, should not be permitted to end before it has established an international code of medicine; thus, everything contributes at present to make this problem timely and to prepare a solution for the greater good of humanity.

For the first time in the history of the world, a war has ended in trial of the belligerents whose conduct had not conformed to international law or to the obligations which had been countersigned by the interested high contracting parties. What is even more important, physicians have been prosecuted for acts of "lèse-humanité."

The Nuremberg trials ought not to end with this verdict; they contain lessons from which the entire medical world ought to profit.

What are these lessons? First, the medical conscience cannot be subjugated to a government or to a state; it must derive its discipline from a moral sanction superior to the concept of the state; there should not be an obligation to obey orders which deprive the physician of his healing mission.

Furthermore, the physician's healing mission must be extended to all the wounded and sick, whatever their nationality or their race. A physician does not have the right to refuse to care for a human being under the pretext that he is an enemy of his country, and, as a parallel to this, no authority has the right to reproach a physician for having given aid, in any circumstances whatever, to a human being whose condition requires it.

These are the principles which it is absolutely necessary to formulate in the work which is beginning, and it can be said that the moment is opportune to bring it to a satisfactory conclusion. In fact, numerous medical assemblies have considered this great question and in the texts which they have published they have affirmed this necessity.

The Congress of Microbiology at Copenhagen has:

> proposed to support and adopt by acclamation that the Fourth International Congress of Microbiology together with the International Society of Cytology condemns as energetically as possible all forms of biologic warfare. The Congress believes that these absolutely barbaric methods are incompatible with any civilized community and hopes much that microbiologists of the entire world will make all efforts to prevent their own exploitation for this purpose.

The World Medical Association demands that every physician take an oath which regulates his professional conduct.

The International Committee of Military Medicine demands that there be added to the text of this oath the following paragraph:

> My duty, superior to all others, written or not written, will be to care to the best of my ability for him who has been placed in my care or who has entrusted himself to me, to respect his moral liberty and to be opposed to all cruelty which is attempted against him and to refuse my cooperation to any authority which request me to act contrary to this demand. Whether the patient be friend or enemy, even in time of war or civil disturbances, whatever be his opinion, his race, his party, his social class, his country, his connection, my care and my aid to his human dignity will be the same.

Thus, it is the international medical code which has to be reformulated. With this aim the Medico-Legal Committee of the International Committee of Military Medicine has proposed to prepare a codification of these regulations.

This is based on the following points:

1. The physician must render the same aid to his friend or to his enemy.
2. In no case should the physician be disturbed at having given aid to a wounded person whatever the nationality, race, religion or opinion of the injured, and whatever may be the circumstances in which the wounded is found.
3. The physician can never in any manner cooperate in works of general or individual destruction.
4. As a result, this set of duties confers on the physician a legal status, according to which he cannot be made a prisoner and according to which he must be granted in all times, and in all places, the right of his complete professional freedom.

This is the proposal set forth by the International Committee of Military Medicine. The World Health Organization and the World Medical Organization, in our opinion, should take a stand as soon as possible on this problem which affects the future of all medicine.

## *Clinical Notes, Suggestions and New Instruments*

### ANAPHYLACTIC DEATH FROM PENICILLIN

GEORGE L. WALDBOTT, M.D.
Detroit

Most allergic reactions from penicillin occur a few days after its administration, namely, as serum sickness or dermatitis. Such manifestations as asthma, vasomotor rhinitis or urticaria arising within a few hours are much less common. A search of the literature reveals no case reports of anaphylactic[1] shock from injections of penicillin. In one instance so designated[1a] there were symptoms of serum sickness.

The following fatality from penicillin is reported here because it represents typical anaphylactic shock. The circumstances leading to death conformed in every respect with my knowledge of this syndrome gained from experience with injections of horse serum, pollen and other antigenic substances.[2]

#### REPORT OF A CASE

Miss L. K., 39 years old, had had severe bronchial asthma since March 1945, which followed grass hay fever of eighteen years' duration and had been persistent since July 1946. Thorough diagnostic studies had been made, including roentgenograms of the chest, bronchograms, diagnostic bronchoscopic studies and intradermal tests. These revealed allergic asthma associated with decided emphysema and considerable emaciation. The patient had received the usual symptomatic treatment and a thorough hyposensitization regimen, both at a large allergy center and, since March 1948, in my office. Progress had been slow but steady; the attacks appeared less frequently; there was a gain in weight of 14 pounds (6 Kg.).

She stated that she had had penicillin for the first time in April 1947, receiving intramuscular injections every three hours for seven days. A second course, in May 1948, consisted of four daily doses of 300,000 units of procaine penicillin ;a third course, on June 30, consisted of 400,000 units administered in doses of 50,000 units every three hours. At no time had there been any ill effect from this therapy, and it was always followed by improvement of the asthma.

On August 18 at 10 a. m. she presented herself at the office with general malaise and temperature up to 101.5 F. of two days' duration. Examination of the chest showed asthmatic wheezing combined with some rales throughout the lungs. The patient was again given 2 vials of penicillin containing 200,000 units each, which was to be administered by her sister, a registered nurse, in doses of 50,000 units. She received her routine hyposensitization treatment (consisting of 2,800 units of short and long ragweed, 600 units of English plantain combined with 0.1 cc. of an extract of alternaria, monilia, torula, smut and yeast) and, in addition, ⅓ of a 3¾ grain ampule (0.08 Gm.) of aminophylline intravenously. When she left the office, after thirty minutes, the site of the antigenic injection showed no unusual degree of local edema and the wheezing had improved from the administration of aminophylline. After arrival at her home, she had only one slight coughing spell during luncheon (12:30 p. m.), but otherwise felt comfortable. At about 1:45 p. m., the first dose of penicillin (50,000 units) was administered into the gluteal region. Within five seconds the patient complained of a strange taste in her mouth and tongue and swelling and tightness in the throat and nose; her face became flushed, bloated and extremely cyanotic; she felt itchy "all over." Leaning over the kitchen table and asking for a glass of water, she collapsed and died immediately.

#### COMMENT

Although no autopsy could be done, the diagnosis of anaphylactic shock appears definite because of the characteristic symptoms (tightness in nose and throat, severe dyspnea associated with urticaria) and because of the onset within a few seconds after the hypodermic administration of penicillin. That the injection must have been given intravenously through accidental puncture of a vein is indicated by the appearance of blood at the site of injection and by the "strange taste" in the mouth which is so characteristic in intravenous therapy[3]—an ominous sign to anyone who deals constantly with allergic persons. The patient had had no drug or medication other than the routine antigenic injections given four hours previously; this could not have accounted for this accident.[2]

It must be assumed that sensitization to penicillin resulted from previous injections; otherwise the patient could not have tolerated the preceding penicillin treatment as well as she did. She would have had some manifestation of allergy, probably an aggravation of the asthma. I have seen severe asthma occur in 1 case shortly after the initiation of a second course of penicillin and in another after the first injection of a third course. In the former the attack was so severe that it required several days of intensive treatment before its effect was overcome. It is likely that in this case death would have resulted had the injection of penicillin been made intravenously. In the other patient, the asthmatic seizure was less severe and protracted.

In a review of my record, it was noted that this patient had had severe urticaria, some aggravation of asthma, joint pains and slight fever during the first part of July, about one week after the administration of penicillin. This had not been identified at the time as serum sickness from penicillin, but in all probability presented the outward signs of the development of sensitization to penicillin.

From the point of view of prophylaxis the following points should be emphasized. 1. One should always carefully inquire into the history of serum sickness from previous penicillin injections. Such a history should constitute a warning that sensitization to the drug might exist. 2. Intradermal tests, regardless of certain limitations in their usefulness, are still the best method for detecting sensitivity.[4] In any allergic patient who has had previous injections of penicillin, intradermal tests should be given at first with doses as low as 100 to 300 units; if results are negative, larger doses of 3,000 and 5,000 units may be used for intradermal tests after a fifteen minute interval. "Late" reactions occurring the following day have no bearing on such immediate manifestations of allergy as described herein. 3. If there is any indication of sensitization, intravenous administration of penicillin should be avoided. The usual precaution for avoidance of accidental intravenous injections should be carried out in the use of penicillin,[3] e. g., withdrawal of plunger for evidence of blood before the injection is made.

---

[1] This term, I believe, is preferable to "allergic" shock, as a distinction between the two can no longer be upheld.

As with other medications, more extended use of this drug will without doubt bring forth additional cases of this kind. The condition will occur in patients exhibiting other allergic sensitivities as well as in nonallergic persons who have had penicillin previously, especially if the time lapse between the previous course and the present one approximates the optimal interval for the development of experimental anaphylaxis, namely, two to four weeks.

# Council on Physical Medicine

## REPORTS OF THE COUNCIL

*The Council on Physical Medicine has authorized publication of the following reports.* Howard A. Carter, *Secretary.*

### AN APPRECIATION

The Council on Physical Medicine desires to take this opportunity to express its feelings of gratitude and appreciation for the services of the following consultants, whose assistance in carrying out the work of the Council has been given so freely during the past year: Drs. Edward Bigg, Raymond Carhart, Mrs. Eva Thompson Carson, Drs. Milton B. Cohen, M. Edward Davis, David C. Fainer, Theodore Friedemann, Clarence J. Gamble, Emil D. W. Hauser, W. D. Hawker, George Holmes, Helen Holt, Ernest Irons, Mr. Richard E. Jones, Drs. Mary Karp, H. Worley Kendell, Margarete M. Kunde, Claude N. Lambert, Victoire Lespinasse, Edwin R. Levine, Alfred Lewy, E. O. Molander, Arthur Mutscheller, Louis B. Newman, Benjamin H. Orndoff, Stafford L. Osborne, Scott N. Reger, Joseph Remlinger, Henry Schwerma, Ronald Simpson, G. deTakats, O. E. Van Alyea, Paul Wosika and C. R. Zeiss.

*American Health Resorts.*—Drs. Frances Hellebrandt, Miletus B. Jarman, Walter McClellan and Euclid Smith.

*Artificial Limbs.*—Drs. Rufus H. Alldredge, Henry H. Kessler and Paul E. Klopsteg and Messrs. Lucius Trautman and J. B. Korrady.

*Medical Aspects of Atomic Energy.*—Drs. Kenneth S. Cole, L. F. Curtiss, Hymer L. Friedell, Shields Warren and Stafford L. Warren.

*Audiometers and Hearing Aids.*—Drs. Gordon Berry, Hallowell Davis, Kenneth M. Day, E. P. Fowler, Isaac H. Jones, Dean Lierle, Moses H. Lurie, Douglas Macfarlan, C. Stewart Nash and Paul E. Sabine.

*Clinical Thermometry.*—Miss Johanna Busse and Drs. George Crile Jr., Eugene Du Bois, Steven M. Horvath, John Talbot and George Thorn.

*Contraceptive Devices.*—Drs. William W. Greulich, Joseph Hughes and Prof. Walter J. Meek, Mr. R. R. Olin and Drs. Ephraim Shorr and Pendleton Tompkins.

*Education.*—Drs. Frances Baker, Robert L. Bennett, Ben L. Boynton, Earl C. Elkins, F. H. Ewerhardt (deceased), Richard Kovacs, Fred B. Moor, William H. Northway, William H. Schmidt, Walter M. Solomon, Arthur L. Watkins, George D. Wilson and Walter J. Zeiter.

*Electrocardiographs.*—Drs. A. R. Barnes, George Fahr, Harold E. B. Pardee, William D. Stroud, Carl J. Wiggers and Frank N. Wilson.

*Electroencephalographs.*—Drs. Percival Bailey, Edward J. Baldes, Stanley Cobb, Hallowell Davis and Frederic A. Gibbs.

*Occupational Therapy.*—Drs. Raymond B. Allen, Robert W. Johnson Jr., Winfred Overholser, Howard A. Rusk and William D. Stroud.

*Ophthalmic Devices.*—Drs. Thomas D. Allen, David G. Cogan, William F. Hughes Jr., Richard Scobee and Kenneth C. Swan.

*Respirators.*—Drs. Edward L. Compere, Charles F. McKhann and James L. Wilson.

*Roentgen Rays and Radium.*—Drs. W. Edward Chamberlain, Arthur C. Christie, Edwin C. Ernst, Gioacchino Failla, Fred M. Hodges, R. R. Newell, Eugene P. Pendergrass, Ursus V. Portmann, Lauriston S. Taylor and J. L. Weatherwax.

### PUR-AR-LITE GERMICIDAL AIR-PURIFIER NOT ACCEPTABLE

Manufacturer: Circlite Corporation, 118 South Clinton Street, Chicago 6.

The Pur-Ar-Lite Germicidal Air-Purifier 4 Watt Pin-Up Lamp is designed to be hung on the wall and to direct a portion of its rays into the upper parts of a room. The firm claims that this lamp may be used "in the kitchen," "in the bedroom," "in the bathroom" and "in public places"; that it "helps protect children and adults from colds, dangerous diseases, cuts down on doctor bills!" "helps keep air fresh, clean, sweet-smelling always" in "washrooms, restaurants, food stores, offices, hospitals . . . helps keep air pure, germ and odor-free" and "destroys cooking odors, bread box molds, preserves food longer in refrigerators!"

The unit consists essentially of two parts, a lamp source manufactured by the Sylvania Electric Products Co., Inc., and a fixture manufactured by the Circlite Corporation. The lamp draws 0.36 ampere on a 110-120 volt alternating current. The disinfecting radiation emitted by this lamp comes from a glow-discharge in mercury vapor and is mainly of wavelength 2,537 angstroms. The dimensions of the fixture are 23 by 7 by 6.4 cm. (9 by 2¾ by 2½ inches); it weighs 680 Gm. (1½ pounds). The shipping weight is 0.8 Kg. (1¾ pounds).

The housing for the lamp consists of a highly polished aluminum box, cylindric in front and flat at the back to permit hanging on the wall. Holes at the bottom and top of the box facilitate ventilation and circulation of air close to the lamp source housed within.

The evidence submitted by the firm to substantiate the electrical and physical characteristics was confirmed by the Council. The ultraviolet intensities observed at a distance of 1 meter were as follows: (1) for the bare lamp, $1.4\ \mu W/cm.^2$, and (2) for the lamp in its housing, $1.2\ \mu W/cm.^2$. These data show that the intensity of the 4 watt disinfecting lamp unit is only about 1/20 of the value of a single 30 watt lamp unit accepted by the Council.

After careful investigation, the Council held that this lamp is not effective to do that which is claimed for it. The firm submitted insufficient evidence to substantiate the claims, as for example the "Pur-Ar-Lite Air Purifier . . . the miracle of modern science . . protects your family, your home from deadly air-borne bacteria . . . eliminates disagreeable odors," or the claim the "Pur-Ar-Lite guards your family against disease" and the "Pur-Ar-Lite Air Purifier's powerful concentrated ultraviolet light rays quickly, instantly deal a death blow to menacing air-borne germs which spread colds, sore throats, flu, pneumonia, measles, scarlet fever, diphtheria, smallpox and other dread contagious diseases. Pur-Ar-Lite Air Purifier is a modern scientific method of insuring your family's health!"

The Council on Physical Medicine accepts ultraviolet disinfecting lamps for use in hospitals (one of the applications recommended by the Circlite Corp.), but, since this lamp gives only about 1/20 of the minimum value of a single 30 watt lamp, in the opinion of the Council it would be impractical to equip a hospital ward with a sufficient number of these lamps to be biologically effective in an enclosure containing a regimented population.

The Pur-Ar-Lite is pictured in the advertising as hanging on the wall, in the bedroom, in the bathroom and in public places. In the manner in which it is recommended for use the Council is not convinced in view of the evidence available that the Pur-Ar-Lite will provide any protection against cross infection of "colds, sore throats, flu, pneumonia, measles, scarlet fever, diphtheria, smallpox and other dread contagious diseases."

The Council on Physical Medicine voted not to accept the Pur-Ar-Lite Germicidal Air-Purifier Lamp for inclusion in its list of accepted devices because (1) the ultraviolet radiation is too weak to be effective for acceptable installations and (2) critical evidence has not been presented by the promoter to substantiate the claims made for it in other installations.

## AMERICAN MEDICAL ASSOCIATION PROGRAM FOR THE ADVANCEMENT OF MEDICINE AND PUBLIC HEALTH

On the page opposite appears the text of the expanded program of the American Medical Association developed over a period of years with a view to charting a safe and sure road toward advancement of the nation's health. Many of the planks in this platform have been advanced by the American Medical Association for many years. Thus the American Medical Association has urged the creation of a Federal Department of Health of cabinet status, in which all federal health activities could be coordinated and integrated, for more than seventy-five years.

The National Science Foundation bill was passed in 1948 by both the Senate and the House and vetoed by the President because of differences on the manner of administration. No doubt such differences of opinion will be adjusted and this measure will become effective.

The American Medical Association is now committed to urging the widest possible extension of sound systems of voluntary prepayment plans to meet the costs of hospital and medical care. Much confusion has resulted from differences of opinion as to how such extension could be best achieved, whether by a national insurance company, which would combine Blue Cross and Blue Shield plans, or by a coordination of voluntary and private prepayment plans into a single organization which would contract with the Blue Cross for various services. During the past week extensive negotiations have been held among those especially interested in this phase of the problem, and steady progress is being made toward a mutually satisfactory solution.

Among the difficulties in meeting the problems of persons in the low income group and of the indigent is the difficulty of utilizing funds developed by the individual states and the federal government without the establishment of a great new bureaucracy or the nationalization of health activities. The proposal has been made that there be established in each state a medical care authority or board which could receive such funds and distribute them where the need could be shown. The Association recognizes the right of the consumer in planning for medical care and urges proper representation of both medical and consumer interests on such state medical care authorities.

Today in the United States all persons properly informed as to medical conditions recognize the need for the establishment of diagnostic facilities and health centers, particularly in remote areas in which physicians dislike to practice because provision is not made for the use of technics of clinical pathology and roentgen ray, which are inseparable from good medical practice. The American Medical Association recognizes that funds have already been provided by the National Hospital Survey and Construction Act not only for the extension of hospital services but also for the development of diagnostic facilities and health centers. Notwithstanding the fact that every one concerned urged the passage of this act, the actual functioning has been pitifully slow. Whether or not the delay can be laid to local, state or national agencies concerned in this phase of progress, the fact remains that the leadership that should have come from federal agencies in promoting properly the development of these facilities has been noticeable by its absence.

All the health agencies in the United States are urging the extension of local public health units and services throughout the nation. Again and again leaders have pointed out that almost half of the counties in the United States are without such services. Through such local public health units the control of communicable diseases and of venereal diseases may be exercised. Here the vital statistics for the community may be assembled. In such agencies plans may be devised for maternal and child hygiene and for the extension of sewage facilities, which are lacking in thousands of communities. Here also the public health center may be located and public health laboratory services maintained. Notwithstanding the forward looking aspects of this program, every one should recognize that the greatest lack is in personnel. Our public health schools do not develop enough public health officials to meet the need, and technicians in all the accessory professions are also in short supply. Finally, the remuneration of public health officials is ridiculously small in view of the tremendous responsibilities that they carry for the health of the people.
